

Monte Carlo Algorithms

- The randomized bipartite perfect matching algorithm is called a **Monte Carlo algorithm** in the sense that
 - If the algorithm finds that a matching exists, it is always correct (**no false positives**).
 - If the algorithm answers in the negative, then it may make an error (**false negatives**).
- The probability that the algorithm makes a false negative is at most 0.5.
- This probability is *not* over the space of all graphs or determinants, but *over* the algorithm's own coin flips.
 - It holds for *any* bipartite graph.

The Markov Inequality^a

Lemma 53 *Let x be a random variable taking nonnegative integer values. Then for any $k > 0$,*

$$\text{prob}[x \geq kE[x]] \leq 1/k.$$

- Let p_i denote the probability that $x = i$.

$$\begin{aligned} E[x] &= \sum_i ip_i \\ &= \sum_{i < kE[x]} ip_i + \sum_{i \geq kE[x]} ip_i \\ &\geq kE[x] \times \text{prob}[x \geq kE[x]]. \end{aligned}$$

^aAndrei Andreyevich Markov (1856–1922).

An Application of Markov's Inequality

- Algorithm C runs in expected time $T(n)$ and always gives the right answer.
- Consider an algorithm that runs C for time $k \times T(n)$ and rejects the input if C does not stop within the time bound.
- By Markov's inequality, this new algorithm runs in time $kT(n)$ and gives the correct answer with probability at least $1 - 1/k$.
- By running this algorithm m times, we reduce the error probability to $\leq k^{-m}$.

A Random Walk Algorithm for ϕ in CNF Form

- 1: Start with an *arbitrary* truth assignment T ;
- 2: **for** $i = 1, 2, \dots, r$ **do**
- 3: **if** $T \models \phi$ **then**
- 4: **return** “ ϕ is satisfiable”;
- 5: **else**
- 6: Let c be an unsatisfiable clause in ϕ under T ; {All of its literals are false under T . }
- 7: Pick any x of these literals *at random*;
- 8: Modify T to make x true;
- 9: **end if**
- 10: **end for**
- 11: **return** “ ϕ is probably unsatisfiable”;

3SAT and 2SAT Again

- Note that if ϕ is unsatisfiable, the algorithm will not refute it.
- The random walk algorithm runs in exponential time for 3SAT.
- But we will show that it works well for 2SAT.

Theorem 54 *Suppose that the random walk algorithm with $r = 2n^2$ is applied to any satisfiable 2SAT problem with n variables. Then a satisfying truth assignment will be discovered with probability at least 0.5.*

The Proof

- Let \hat{T} be a truth assignment such that $\hat{T} \models \phi$.
- Let $t(i)$ denote the expected number of repetitions of the flipping step until a satisfying truth assignment is found if our starting T differs from \hat{T} in i values.
 - Their Hamming distance is i .
- It can be shown that $t(i)$ is finite.
- $t(0) = 0$ because it means that $T = \hat{T}$ and hence $T \models \phi$.
- If $T \neq \hat{T}$ or T is not equal to any other satisfying truth assignment, then we need to flip at least once.

The Proof (continued)

- We flip to pick among the 2 literals of a clause not satisfied by the present T .
- At least one of the 2 literals is true under \hat{T} , because \hat{T} satisfies all clauses.
- So we have at least 0.5 chance of moving closer to \hat{T} .
- Thus

$$t(i) \leq \frac{t(i-1) + t(i+1)}{2} + 1$$

for $0 < i < n$.

- Inequality is used because, for example, T may differ from \hat{T} in both literals.

The Proof (continued)

- It must also hold that

$$t(n) \leq t(n-1) + 1$$

because at $i = n$, we can only decrease i .

- As we are only interested in upper bounds, we solve

$$x(0) = 0$$

$$x(n) = x(n-1) + 1$$

$$x(i) = \frac{x(i-1) + x(i+1)}{2} + 1, \quad 0 < i < n$$

- This is one-dimensional random walk with a reflecting and an absorbing barrier.

The Proof (continued)

- Add the equations up to obtain

$$\begin{aligned} & x(1) + x(2) + \cdots + x(n) \\ = & \frac{x(0) + x(1) + 2x(2) + \cdots + 2x(n-2) + x(n-1) + x(n)}{2} \\ & + n + x(n-1). \end{aligned}$$

- Simplify to yield

$$\frac{x(1) + x(n) - x(n-1)}{2} = n.$$

- As $x(n) - x(n-1) = 1$, we have

$$x(1) = 2n - 1.$$

The Proof (continued)

- Iteratively, we obtain

$$x(2) = 4n - 4$$

⋮

$$x(i) = 2in - i^2$$

- The worst case happens when $i = n$, in which case

$$x(n) = n^2.$$

The Proof (continued)

- We therefore reach the conclusion that

$$t(i) \leq x(i) \leq x(n) = n^2.$$

- So the expected number of steps is at most n^2 .
- The algorithm picks a running time $2n^2$.
- This amounts to invoking the Markov inequality (p. 282) with $k = 2$, with the consequence of having 0.5 probability.

Boosting the Performance

- We can pick $r = 2mn^2$ to have an error probability of $\leq (2m)^{-1}$ by Markov's inequality.
- Alternatively, with the same running time, we can run the $r = 2n^2$ algorithm m times.
- But the error probability is reduced to $\leq 2^{-m}$!
- The gain comes from the fact that Markov's inequality does not take advantage of any specific feature of the random variable.
- The gain also comes from the fact that the two algorithms are different.

The Fermat Test

- Fermat’s “little” theorem on p. 262 suggests the following primality test for any given number p :
 - Pick a number a randomly from $\{1, 2, \dots, p - 1\}$.
 - If $a^{p-1} \neq 1 \pmod p$, then declare “ p is composite.”
 - Otherwise, declare “ p is probably prime.”
- Unfortunately, there are composite numbers called **Carmichael numbers** that will pass the Fermat test for *all* $a \in \{1, 2, \dots, p - 1\}$.
- It is only recently that Carmichael numbers are known to be infinite in number.

Square Roots Modulo a Prime

- Equation $x^2 = a \pmod{p}$ has at most two (distinct) roots by Lemma 50 on p. 264.
 - The roots are called **square roots**.
 - Numbers a with square roots and $\gcd(a, p) = 1$ are called **quadratic residues**:
 - $1^2 \pmod{p}, 2^2 \pmod{p}, \dots, (p-1)^2 \pmod{p}$.
 - $x^2 = a \pmod{p}$ has at most two roots when p is odd.
- We shall show that a number either has two roots or has none, and testing which is true is trivial.

Euler's Test

Lemma 55 (Euler) *Let p be an odd prime and $a \not\equiv 0 \pmod{p}$.*

- 1. If $a^{(p-1)/2} \equiv 1 \pmod{p}$, then $x^2 \equiv a \pmod{p}$ has two roots.*
 - 2. If $a^{(p-1)/2} \not\equiv 1 \pmod{p}$, then $a^{(p-1)/2} \equiv -1 \pmod{p}$ and $x^2 \equiv a \pmod{p}$ has no roots.*
- Let r be a primitive root of p .
 - If $a \equiv r^{2j}$, then $a^{(p-1)/2} \equiv r^{j(p-1)} \equiv 1 \pmod{p}$ and its two distinct roots are $r^j, -r^j$ ($\equiv r^{j+(p-1)/2}$).

The Proof (continued)

- Since there are $(p - 1)/2$ such a 's, and each such a has two distinct roots, we have run out of *square roots*.
 - $\{c : c^2 = a \bmod p\} = \{1, 2, \dots, p - 1\}$.
- If $a = r^{2j+1}$, then it has no roots because all the square roots are taken.
- By Fermat's "little" theorem, $r^{(p-1)/2}$ is a square root of 1, so $r^{(p-1)/2} = \pm 1 \bmod p$.
- But as r is a primitive root, $r^{(p-1)/2} = -1 \bmod p$.
- $a^{(p-1)/2} = (r^{(p-1)/2})^{2j+1} = (-1)^{2j+1} = -1 \bmod p$.

The Legendre Symbol^a and Quadratic Residuacity Test

- So $a^{(p-1)/2} \pmod p = \pm 1$ for $a \not\equiv 0 \pmod p$.
- For odd prime p , define the **Legendre symbol** $(a | p)$ as

$$(a | p) = \begin{cases} 0 & \text{if } p | a \\ 1 & \text{if } a \text{ is a quadratic residue modulo } p \\ -1 & \text{if } a \text{ is a quadratic nonresidue modulo } p \end{cases}$$

- Euler's test implies $a^{(p-1)/2} \equiv (a | p) \pmod p$ for any odd prime p and any integer a .
- Note that $(ab|p) = (a|p)(b|p)$.

^aAndrien-Marie Legendre (1752–1833).

Gauss's Lemma

Lemma 56 (Gauss) *Let p and q be two odd primes. Then $(q|p) = (-1)^m$, where m is the number of residues in $R = \{iq \bmod p : 1 \leq i \leq (p-1)/2\}$ that are greater than $(p-1)/2$.*

- All residues in R are distinct.
 - If $iq = jq \bmod p$, then $p|(j-i)$ or $p|q$.
- No two elements of R add up to p .
 - If $iq + jq = 0 \bmod p$, then $p|(i+j)$ or $p|q$.
- Consider the set R' of residues that result from R if we replace each of the m elements $a \in R$ where $a > (p-1)/2$ by $p-a$.

The Proof (continued)

- All residues in R' are now at most $(p - 1)/2$.
- In fact, $R' = \{1, 2, \dots, (p - 1)/2\}$.
 - Otherwise, two elements of R would add up to p .
- Alternatively, $R' = \{\pm iq : 1 \leq i \leq (p - 1)/2\}$, where exactly m of the elements have the minus sign.
- Taking the product of all elements in the two representations of R' , we have
$$[(p - 1)/2]! = (-1)^m q^{(p-1)/2} [(p - 1)/2]! \pmod{p}.$$
- Because $\gcd([(p - 1)/2]!, p) = 1$, the lemma follows.

Legendre's Law of Quadratic Reciprocity

- Let p and q be two odd primes.
- Then their Legendre symbols are identical unless both numbers are $3 \pmod{4}$.

Lemma 57 (Gauss) $(p|q)(q|p) = (-1)^{\frac{p-1}{2}\frac{q-1}{2}}$.

- Sum the elements of R' in the previous proof in $\text{mod } 2$.
- On one hand, this is just

$$\sum_{i=1}^{(p-1)/2} i = \frac{(p-1)(p+1)}{8} \pmod{2}.$$

The Proof (continued)

- On the other hand, the sum equals

$$q \sum_{i=1}^{(p-1)/2} i - p \sum_{i=1}^{(p-1)/2} \left\lfloor \frac{iq}{p} \right\rfloor + mp \pmod{2}.$$

- Signs are irrelevant under mod 2.
- After ignoring odd multipliers and noting that the first term above equals $\sum_{i=1}^{(p-1)/2} i$:

$$m = \sum_{i=1}^{(p-1)/2} \left\lfloor \frac{iq}{p} \right\rfloor \pmod{2}.$$

The Proof (continued)

- $m = \sum_{i=1}^{(p-1)/2} \lfloor \frac{iq}{p} \rfloor$ is the number of positive integral points in the $\frac{p-1}{2} \times \frac{q-1}{2}$ rectangle that are under the line between $(0, 0)$ and the point (p, q) .
- From Gauss's lemma on p. 298, $(q|p)$ is $(-1)^m$.
- Repeat the proof with p and q reversed.
- We obtain $(p|q)$ is -1 raised to the number of positive integral points in the $\frac{p-1}{2} \times \frac{q-1}{2}$ rectangle that are above the line between $(0, 0)$ and the point (p, q) .
- So $(p|q)(q|p)$ is -1 raised to the total number of integral points in the $\frac{p-1}{2} \times \frac{q-1}{2}$ rectangle, which is $\frac{p-1}{2} \cdot \frac{q-1}{2}$.

Eisenstein's Rectangle

$p = 11$ and $q = 7$.

The Jacobi Symbol^a

- The Legendre symbol only works for an odd prime modulus.
- The **Jacobi symbol** $(a | m)$ extends it to cases where m is not prime.
- Let $m = p_1 p_2 \cdots p_k$ be the prime factorization of m .
- When m is odd and is greater than one, then

$$(a | m) = \prod_{i=1}^k (a | p_i).$$

- Define $(a | 1) = 1$.

^aCarl Jacobi (1804–1851).

Properties of the Jacobi Symbol

The Jacobi symbol has the following properties, for arguments for which it is defined.

1. $(ab \mid m) = (a \mid m)(b \mid m)$.
2. $(a \mid m_1 m_2) = (a \mid m_1)(a \mid m_2)$.
3. If $a \equiv b \pmod{m}$, then $(a \mid m) = (b \mid m)$.
4. $(-1 \mid m) = (-1)^{(m-1)/2}$.
5. $(2 \mid m) = (-1)^{(m^2-1)/8}$.
6. If a and m are both odd, then $(a \mid m)(m \mid a) = (-1)^{(a-1)(m-1)/4}$.

Calculation of $(2200|999)$

Similar to the Euclidean algorithm and does *not* require factorization.

$$\begin{aligned}(202|999) &= (-1)^{(999^2-1)/8} (101|999) \\ &= (-1)^{124750} (101|999) = (101|999) \\ &= (-1)^{(100)(998)/4} (999|101) = (-1)^{24950} (999|101) \\ &= (999|101) = (90|101) = (-1)^{(101^2-1)/8} (45|101) \\ &= (-1)^{1275} (45|101) = -(45|101) \\ &= -(-1)^{(44)(100)/4} (101|45) = -(101|45) = -(11|45) \\ &= -(-1)^{(10)(44)/4} (45|11) = -(45|11) \\ &= -(1|11) = -(11|1) = -1.\end{aligned}$$

The Jacobi Symbol and Primality Test^a

Lemma 58 *If $(M|N) = M^{(N-1)/2} \pmod N$ for all $M \in \Phi(N)$, then N is prime. (Assume N is odd.)*

- First assume that $N = rp^a$, where p is an odd prime, $\gcd(r, p) = 1$, $r > 1$ (not necessarily prime), and a is odd.
- We shall derive a contradiction.
- By the assumption,

$$M^{(N-1)/2} = \pm 1 \pmod N \text{ for all } M \in \Phi(N). \quad (3)$$

- Suppose $M^{(N-1)/2} = -1 \pmod N$ for some $M \in \Phi(N)$.

^aClement Hsiao pointed out that the textbook's proof in Lemma 11.8 is incorrect when he was a senior.

The Proof (continued)

- Then there is a unique M' such that

$$M' = 1 \pmod{r}$$

$$M' = M \pmod{p^a}$$

by the Chinese remainder theorem.

- As $\gcd(1, r) = \gcd(M, p^a) = 1$, we have $M' \in \Phi(N)$.
- Now

$$M'^{(N-1)/2} = 1 \pmod{r}$$

$$M'^{(N-1)/2} = -1 \pmod{p^a}$$

The Proof (continued)

- But $M'^{(N-1)/2} \neq \pm 1 \pmod{N}$.
 - Otherwise,

$$M'^{(N-1)/2} \pmod{r} = M'^{(N-1)/2} \pmod{p^a}.$$

- This contradicts Eq. (3).
- Hence

$$M^{(N-1)/2} = 1 \pmod{N} \text{ for all } M \in \Phi(N). \quad (4)$$

The Proof (continued)

- By the Chinese remainder theorem again, there is a unique $M' \in \{0, 1, \dots, rp - 1\}$ such that

$$M' \equiv 1 \pmod{r}$$

$$M' \equiv z \pmod{p}$$

where z is one of the quadratic nonresidues modulo p .

- As $\gcd(1, r) = \gcd(z, p) = 1$, $M' \in \Phi(rp)$ and so $M' \in \Phi(N)$.
- $(M'|N) = (M'|r)(M'|p^a) = (M'|r)(M'|p)^a = (1|r)(z|p) = -1$, contradiction Eq. (4).

The Proof (continued)

- Second, assume $N = p_1 p_2 \cdots p_k$, where p_i are distinct odd primes.
- Let $r \in \Phi(p_1)$ such that $(r | p_1) = -1$.
- By the Chinese remainder theorem, there is an $M \in \Phi(N)$ such that

$$M \equiv r \pmod{p_1}$$

$$M \equiv 1 \pmod{p_i}, \quad 2 \leq i \leq k$$

The Proof (continued)

- By the hypothesis,

$$M^{(N-1)/2} = (M \mid N) = \prod_{i=1}^k (M \mid p_i) = -1 \pmod{N}.$$

- Hence

$$M^{(N-1)/2} = -1 \pmod{p_2}.$$

- But because $M = 1 \pmod{p_2}$,

$$M^{(N-1)/2} = 1 \pmod{p_2},$$

a contradiction again.

The Number of Witnesses to Compositeness

Theorem 59 *If N is an odd composite, then*

$(M|N) \neq M^{(N-1)/2} \pmod N$ for at least half of $M \in \Phi(N)$.

- By Lemma 58 there is at least one $a \in \Phi(N)$ such that $(a|N) \neq a^{(N-1)/2} \pmod N$.
- Let $B = \{b_1, b_2, \dots, b_k\} \subseteq \Phi(N)$ be the set of all distinct residues such that $(b_i|N) = b_i^{(N-1)/2} \pmod N$.
- Let $aB = \{ab_i \pmod N : i = 1, 2, \dots, k\}$

The Proof (continued)

- $|aB| = k$.
 - $ab_i \equiv ab_j \pmod N$ implies $N|a(b_i - b_j)$, which is impossible because $\gcd(a, N) = 1$ and $N > |b_i - b_j|$.
- $aB \cap B = \emptyset$ because
$$(ab_i)^{(N-1)/2} = a^{(N-1)/2} b_i^{(N-1)/2} \neq (a|N)(b_i|N) = (ab_i|N).$$
- Combining the above two results, we know $|B|/\phi(N) \leq 0.5$.

A Polynomial-Time Randomized Algorithm for Primality (or Compositeness)^a

- 1: Pick $M \in \{2, 3, \dots, N - 1\}$ randomly;
- 2: **if** $\text{gcd}(M, N) > 1$ **then**
- 3: **return** “ N is a composite”;
- 4: **else**
- 5: **if** $(M|N) \neq M^{(N-1)/2} \pmod N$ **then**
- 6: **return** “ N is a composite”;
- 7: **else**
- 8: **return** “ N is probably a prime”;
- 9: **end if**
- 10: **end if**

^aSolovay, Strassen, 1977.

Analysis

- The algorithm certainly runs in polynomial time.
- There are no false positives (for COMPOSITENESS).
 - When the algorithm says the number is a composite, it is always correct.
- The probability of a false negative is at most one half.
 - When the algorithm says the number is a prime, it may err.
 - If the input is a composite, then the probability that the algorithm errs is one half.
- The probability of error can be reduced but not eliminated.
