- Applications

Correspondence by block matching

- Points are individually ambiguous
- More unique matches are possible with small regions of images

Correspondence by block matching

Criterion function:

Sum of squared distance

w_L and w_R are corresponding m by m windows of pixels.

We define the window function :

$$W_m(x, y) = \{u, v \mid x - \frac{m}{2} \leq u \leq x + \frac{m}{2}, y - \frac{m}{2} \leq v \leq y + \frac{m}{2}\}$$

The SSD cost measures the intensity difference as a function of disparity :

$$C_r(x, y, d) = \sum_{(u,v) \in W_m(x,y)} [I_L(u, v) - I_R(u - d, v)]^2$$

Image blocks as a vector

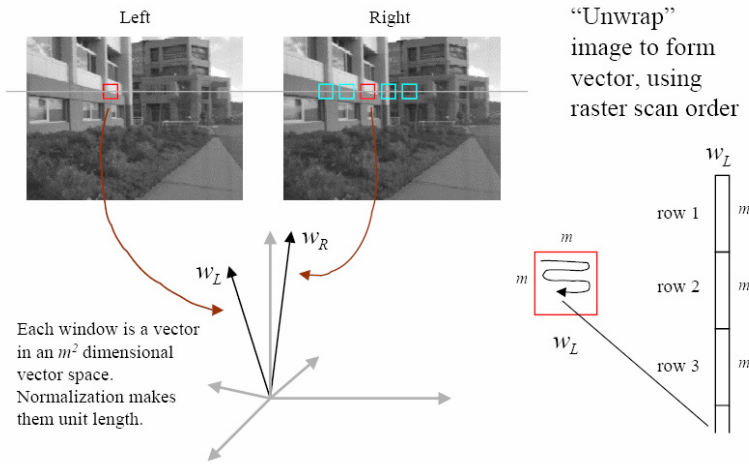

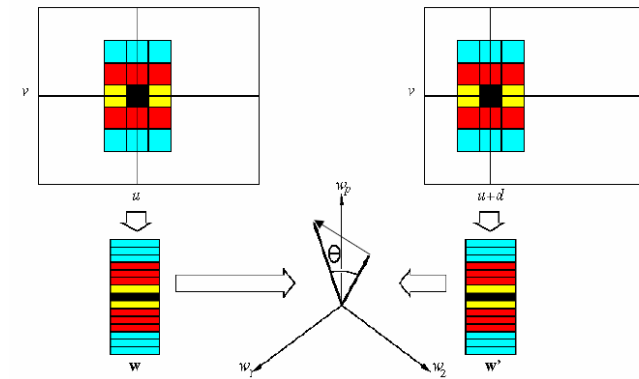

Image blocks as a vector

Matching metrics

Features

- Properties of features
- Detector: locates feature
- Descriptor and matching metrics: describes and matches features
- In the example for block matching:
 - Detector: none
 - Descriptor: block
 - Matching: distance

Desired properties for features

DigiVFX

- Invariant: invariant to scale, rotation, affine, illumination and noise for robust matching across a substantial range of affine distortion, viewpoint change and so on.
- Distinctive: a single feature can be correctly matched with high probability

Harris corner detector

Moravec corner detector (1980)

DigiVFX

- We should easily recognize the point by looking through a small window
- Shifting a window in *any direction* should give a *large change* in intensity

Change of intensity for the shift $[u, v]$:

$$E(u, v) = \sum_{x, y} w(x, y) [I(x+u, y+v) - I(x, y)]^2$$

Window
function

Shifted
intensity

Intensity

Window function $w(x, y) =$

1 in window, 0 outside

Four shifts: $(u, v) = (1, 0), (1, 1), (0, 1), (-1, 1)$
Look for local maxima in $\min\{E\}$

Problems of Moravec detector

- Noisy response due to a binary window function
- Only a set of shifts at every 45 degree is considered
- Responds too strong for edges because only minimum of E is taken into account

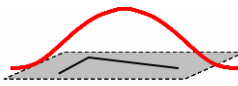

⇒ Harris corner detector (1988) solves these problems.

Harris corner detector

Noisy response due to a binary window function

➤ Use a Gaussian function

$$w(x, y) = \exp\left(-\frac{(x^2 + y^2)}{2\sigma^2}\right)$$

Window function $w(x, y) =$ 
Gaussian

Harris corner detector

Only a set of shifts at every 45 degree is considered

➤ Consider all small shifts by Taylor's expansion

$$\begin{aligned} E(u, v) &= \sum_{x, y} w(x, y) [I(x+u, y+v) - I(x, y)]^2 \\ &= \sum_{x, y} w(x, y) [I_x u + I_y v + O(u^2, v^2)]^2 \end{aligned}$$

$$E(u, v) = Au^2 + 2Cuv + Bv^2$$

$$A = \sum_{x, y} w(x, y) I_x^2(x, y)$$

$$B = \sum_{x, y} w(x, y) I_y^2(x, y)$$

$$C = \sum_{x, y} w(x, y) I_x(x, y) I_y(x, y)$$

Harris corner detector

Equivalently, for small shifts $[u, v]$ we have a *bilinear* approximation:

$$E(u, v) \cong [u, v] M \begin{bmatrix} u \\ v \end{bmatrix}$$

, where M is a 2×2 matrix computed from image derivatives:

$$M = \sum_{x, y} w(x, y) \begin{bmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{bmatrix}$$

Harris corner detector

Responds too strong for edges because only minimum of E is taken into account

➤ A new corner measurement

Harris corner detector

Intensity change in shifting window: eigenvalue analysis

$$E(u, v) \cong [u, v] M \begin{bmatrix} u \\ v \end{bmatrix} \quad \lambda_1, \lambda_2 - \text{eigenvalues of } M$$

Ellipse $E(u, v) = \text{const}$

direction of the fastest change

direction of the slowest change

Harris corner detector

Classification of image points using eigenvalues of M :

λ_1 and λ_2 are small;
 E is almost constant in all directions

Harris corner detector

Measure of corner response:

$$R = \det M - k (\text{trace } M)^2$$

$$\det M = \lambda_1 \lambda_2$$

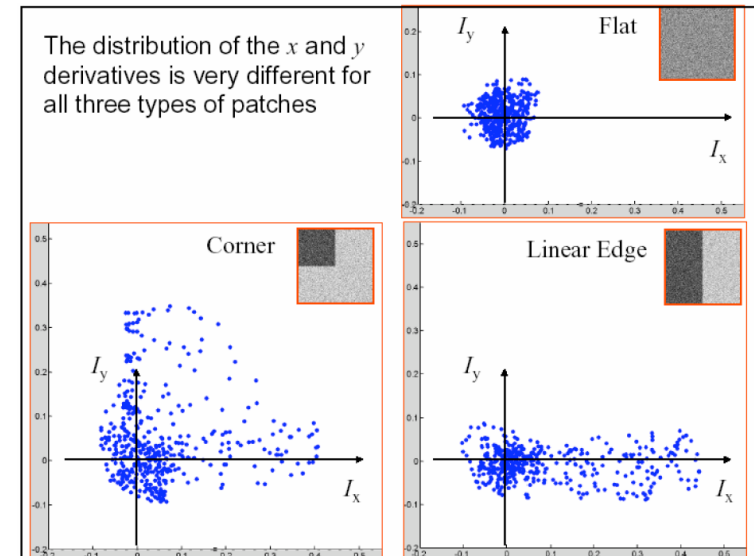

$$\text{trace } M = \lambda_1 + \lambda_2$$

(k - empirical constant, $k = 0.04-0.06$)

Summary of Harris detector

1. Compute x and y derivatives of image

$$I_x = G_\sigma^x * I \quad I_y = G_\sigma^y * I$$

2. Compute products of derivatives at every pixel

$$I_{x2} = I_x \cdot I_x \quad I_{y2} = I_y \cdot I_y \quad I_{xy} = I_x \cdot I_y$$

3. Compute the sums of the products of derivatives at each pixel

$$S_{x2} = G_{\sigma1} * I_{x2} \quad S_{y2} = G_{\sigma1} * I_{y2} \quad S_{xy} = G_{\sigma1} * I_{xy}$$

4. Define at each pixel (x, y) the matrix

$$H(x, y) = \begin{bmatrix} S_{x2}(x, y) & S_{xy}(x, y) \\ S_{xy}(x, y) & S_{y2}(x, y) \end{bmatrix}$$

5. Compute the response of the detector at each pixel

$$R = \text{Det}(H) - k(\text{Trace}(H))^2$$

6. Threshold on value of R . Compute nonmax suppression.

Harris Detector: Summary

- Average intensity change in direction $[u, v]$ can be expressed as a bilinear form:

$$E(u, v) \cong [u, v] M \begin{bmatrix} u \\ v \end{bmatrix}$$

- Describe a point in terms of eigenvalues of M :
measure of corner response

$$R = \lambda_1 \lambda_2 - k(\lambda_1 + \lambda_2)^2$$

- A good (corner) point should have a *large intensity change in all directions*, i.e. R should be large positive

Harris Detector: Some Properties

- Partial invariance to *affine intensity change*

✓ Only derivatives are used =>
invariance to intensity shift $I \rightarrow I + b$

✓ Intensity scale: $I \rightarrow a I$

Harris Detector: Some Properties

- Rotation invariance

Ellipse rotates but its shape (i.e. eigenvalues) remains the same

Corner response R is invariant to image rotation

Harris Detector is rotation invariant

Repeatability rate:

$$\frac{\# \text{ correspondences}}{\# \text{ possible correspondences}}$$

Harris Detector: Some Properties

- But: non-invariant to *image scale*!

All points will be classified as **edges**

Corner !

Harris Detector: Some Properties

- Quality of Harris detector for different scale changes

Repeatability rate:

$$\frac{\# \text{ correspondences}}{\# \text{ possible correspondences}}$$

SIFT
 (**Scale Invariant** Feature Transform)

SIFT

- SIFT is an carefully designed procedure with empirically determined parameters for the invariant and distinctive features.

SIFT stages:

- | | |
|---------------------------------|-------------------|
| • Scale-space extrema detection | detector |
| • Keypoint localization | |
| • Orientation assignment | descriptor |
| • Keypoint descriptor | |

A 500x500 image gives about 2000 features

1. Detection of scale-space extrema

- For scale invariance, search for stable features across all possible scales using a continuous function of scale, scale space.
- SIFT uses DoG filter for scale space because it is efficient and as stable as scale-normalized Laplacian of Gaussian.

DoG filtering

Convolution with a variable-scale Gaussian

$$L(x, y, \sigma) = G(x, y, \sigma) * I(x, y),$$

$$G(x, y, \sigma) = 1/(2\pi\sigma^2) \exp^{-(x^2+y^2)/\sigma^2}$$

Difference-of-Gaussian (DoG) filter

$$G(x, y, k\sigma) - G(x, y, \sigma)$$

Convolution with the DoG filter

$$D(x, y, \sigma) = L(x, y, k\sigma) - L(x, y, \sigma)$$

Scale space

Keypoint localization

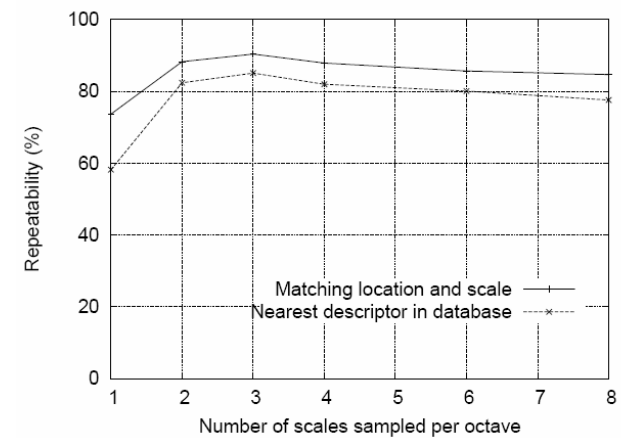

X is selected if it is larger or smaller than all 26 neighbors

Decide scale sampling frequency

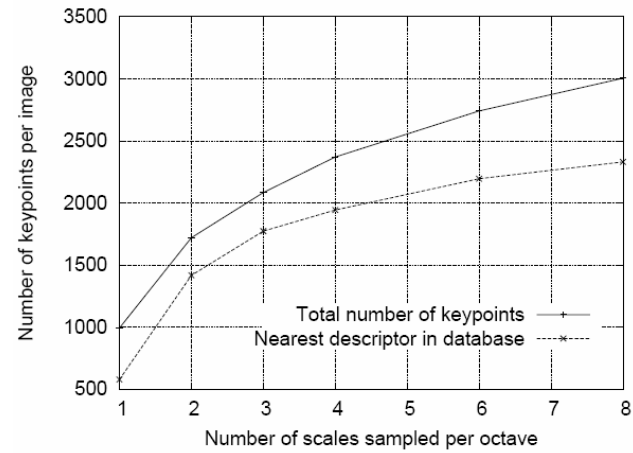

- It is impossible to sample the whole space, tradeoff efficiency with completeness.
- Decide the best sampling frequency by experimenting on 32 real image subject to synthetic transformations.

Decide scale sampling frequency

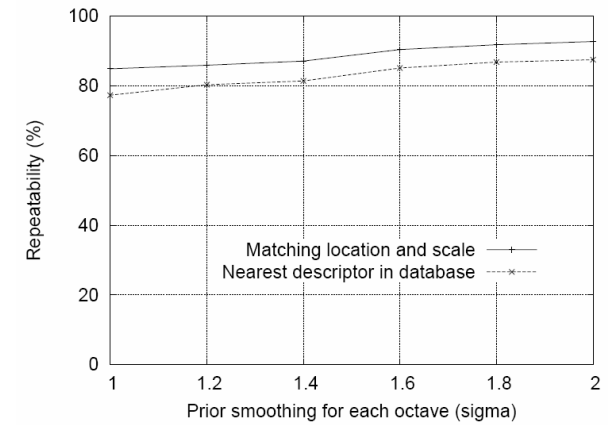

S=3, for larger s, too many unstable features

Decide scale sampling frequency

Pre-smoothing

$\sigma = 1.6$, plus a double expansion

Scale invariance

2. Accurate keypoint localization

- Reject points with low contrast and poorly localized along an edge
- Fit a 3D quadratic function for sub-pixel maxima

Accurate keypoint localization

Taylor expansion (up to the quadratic terms) of the scale-space function, $D(x, y, \sigma)$, shifted so that the origin is at the sample point:

$$D(\mathbf{x}) = D + \frac{\partial D}{\partial \mathbf{x}} \mathbf{x} + \frac{1}{2} \mathbf{x}^T \frac{\partial^2 D}{\partial \mathbf{x}^2} \mathbf{x} \quad (2)$$

where D and its derivatives are evaluated at the sample point and $\mathbf{x} = (x, y, \sigma)^T$ is the offset from this point. The location of the extremum, $\hat{\mathbf{x}}$, is determined by taking the derivative of this function with respect to \mathbf{x} and setting it to zero, giving

$$\hat{\mathbf{x}} = -\frac{\partial^2 D^{-1}}{\partial \mathbf{x}^2} \frac{\partial D}{\partial \mathbf{x}} \quad (3)$$

If $\hat{\mathbf{x}}$ has offset larger than 0.5, sample point is changed.

$$D(\hat{\mathbf{x}}) = D + \frac{1}{2} \frac{\partial D}{\partial \mathbf{x}} \hat{\mathbf{x}}$$

If $|D(\hat{\mathbf{x}})|$ is less than 0.03 (low contrast), it is discarded.

Eliminating edge responses

$$\mathbf{H} = \begin{bmatrix} D_{xx} & D_{xy} \\ D_{xy} & D_{yy} \end{bmatrix}$$

$$\text{Tr}(\mathbf{H}) = D_{xx} + D_{yy} = \alpha + \beta,$$

$$\text{Det}(\mathbf{H}) = D_{xx}D_{yy} - (D_{xy})^2 = \alpha\beta.$$

$$\text{Let } \alpha = r\beta \quad \frac{\text{Tr}(\mathbf{H})^2}{\text{Det}(\mathbf{H})} = \frac{(\alpha + \beta)^2}{\alpha\beta} = \frac{(r\beta + \beta)^2}{r\beta^2} = \frac{(r + 1)^2}{r}$$

$$\text{Keep the points with } \frac{\text{Tr}(\mathbf{H})^2}{\text{Det}(\mathbf{H})} < \frac{(r + 1)^2}{r}, \quad r=10$$

Keypoint detector

(a) 233x189 image
 (b) 832 DOG extrema
 (c) 729 left after peak value threshold
 (d) 536 left after testing ratio of principle curvatures

3. Orientation assignment

- By assigning a consistent orientation, the keypoint descriptor can be orientation invariant.
- For a keypoint, L is the image with the closest scale,

$$m(x, y) = \sqrt{(L(x + 1, y) - L(x - 1, y))^2 + (L(x, y + 1) - L(x, y - 1))^2}$$

$$\theta(x, y) = \tan^{-1}((L(x, y + 1) - L(x, y - 1)) / (L(x + 1, y) - L(x - 1, y)))$$

orientation histogram

Orientation assignment

Orientation assignment

- Keypoint location = extrema location
- Keypoint scale is scale of the DOG image

Orientation assignment

Orientation assignment

Orientation assignment

weighted gradient magnitude

gradient orientation

weighted orientation histogram.
Each bucket contains sum of weighted gradient magnitudes corresponding to angles that fall within that bucket.

36 buckets
10 degree range of angles in each bucket, i.e.
0 <= ang < 10 : bucket 1
10 <= ang < 20 : bucket 2
20 <= ang < 30 : bucket 3 ...

Orientation assignment

weighted gradient magnitude

gradient orientation

weighted orientation histogram.

Orientation of keypoint is approximately 25 degrees

Orientation assignment

There may be multiple orientations.

In this case, generate duplicate keypoints, one with orientation at 25 degrees, one at 155 degrees.

Design decision: you may want to limit number of possible multiple peaks to two.

Orientation assignment

36-bin orientation histogram over 360°, weighted by m and 1.5*scale falloff
Peak is the orientation
Local peak within 80% creates multiple orientations
About 15% has multiple orientations

Orientation invariance

4. Local image descriptor

- Thresholded image gradients are sampled over 16x16 array of locations in scale space
- Create array of orientation histograms
- 8 orientations x 4x4 histogram array = 128 dimensions
- Normalized, clip the components larger than 0.2

Why 4x4x8?
