Project: An Investigation of Python Profilers

Last updated: May 23, 2021

(日)

Introduction I

- Earlier in a project to check the running time of MATLAB and Tensorflow implementations, we could only profile the MATLAB code
- Our Tensorflow code, based on Tensorflow 1.xx, is not procedural
- This seems to make the profiling difficult
- In this project let's consider the package LibMultiLabel at https:

//github.com/ASUS-AICS/LibMultiLabel for multi-label text classification

• It is based on PyTorch and has a procedural setting

Introduction II

- The goal is to do profiling for running this package
- The profiling should be similarly detailed as MATLAB
- The network is simple: one convolutional layer and then one linear layer
- This is also a chance for us to learn how CNN is used for text data
- The package is being actively developed. If changes may affect your projects, we will let you know.

CNN for Text Data I

• Assume each document has the following word embeddings

$$X = \begin{bmatrix} x_1 & \dots & x_N \end{bmatrix} \in R^{d_e \times N},$$

where d_e is the word-embedding dimension and N is the document length.

• That is, by some ways we have already obtained some information for each word

CNN for Text Data II

• For any filter

$$\mathbf{v} \in R^{d_e imes k},$$

a convolutional operation is applied to a text region

$$[\mathbf{x}_n,\ldots,\mathbf{x}_{n+k-1}] \in R^{d_e \times k}$$

of k words

• It is like that we treat X as an image and horizontally extract sub-images

• □ ▶ • 4□ ▶ • Ξ ▶ •

CNN for Text Data III

• Thus the following operation is conducted:

$$(h_n)_j = \sigma(\langle W_{1:d_e,1:k,j}, [\mathbf{x}_n, \ldots, \mathbf{x}_{n+k-1}] \rangle + b_j),$$

where h_n is the *n*th output vector, $\langle \cdot, \cdot \rangle$ is the component-wise sum of two matrices,

$$W_{1:d_e,1:k,j} \in R^{d_e imes k}$$

is the *j*th filter, and σ is an activation function.

< □ > < 同 > < 回 > < Ξ > < Ξ

CNN for Text Data IV

• Here

$$j=1,\ldots,d_c$$

so d_c is the number of filters.

The output after the convolutional operation is a matrix

$$H = \begin{bmatrix} h_1 & \dots & h_{N-k+1} \end{bmatrix} \in R^{d_c \times (N-k+1)}$$

• Assuming the input is not zero-padded

(日)

• The maximum from each row of H is collected

$$g_i = \max_j H_{ij}$$

$$oldsymbol{g} = egin{bmatrix} g_1 & \dots & g_{d_c} \end{bmatrix}^{\mathsf{T}} \in R^{d_c}$$

• This naturally allows for variable document length N

(日)

• The final layer is a linear layer

$$\boldsymbol{z} = A\boldsymbol{g} + \boldsymbol{c} \in R'$$

where $A \in R^{l \times d_c}$ is the weights, c is the bias and l is the number of classes

Multi-label Prediction I

- Each instance belongs to multiple classes
- Thus we cannot take the maximum of *z* as the prediction
- For this project, we do not worry about how predictions are done

Cost Analysis I

Convolutional layer

 $k \times d_e \times d_c \times N$

Pooling layer

 $d_c \times N$

Linear layer

 $I \times d_c$

May 23, 2021

Project Contents I

- See LibMultiLabel README for installation instructions
- Let's run 5 epochs on the rcv1 data and do some analysis
- We will use the kim_cnn architecture (Kim, 2014)
- Check the example in the "Quick Start via Example" section of README
- In kim_cnn.yml you will see a line filter_sizes: [2 4 8]

Project Contents II

This means that different filter sizes are considered. Let's change to use the size of 2 only for easier analysis

- A key thing is to check the running time of major operations and see if things agree with the complexity analysis
- In particular, we check the forward process which is implemented by us. In contrast, the backward process is done by PyTorch
- The usage is

Project Contents III

python3 main.py --cpu --config \
example_config/rcv1/kim_cnn.yml

- For the current setting, the program predicts a test set in the end. Since we are interested only in training, you can remove the test file and the test procedure will not be conducted
- For the training procedure, the code internally splits the training set to 80% for training and 20% for validation
- The validation procedure is used in, for example, deciding when the training procedure should stop

Image: A math a math

Project Contents IV

- Here we do not need that but there is no option yet to disable the validation procedure.
- This is fine because in your comparison between convolutional and linear layers, they are now both run on 80% of data
- To specify parameters, such as the number of epochs, you need to modify the configuration file kim_cnn.yml
- These parameters are specified by the following arguments in the configuration file
 - k: filter_sizes

Project Contents V

- *d_c*: num_filter_per_size
- d_e: it depends on embed_file (e.g. glove.6B.300d is 300)
 Note that for the example we use a pre-trained word embeddings glove.6B.300d

May 23, 2021

17/22

- I: 103 for rcv1
- N: average 123.9 for rcv1

Profiler I

- The package pprofile provides line by line profiling
- Install it by

pip3 install pprofile

- Basic usage is to replace python3 with pprofile pprofile main.py arg1 arg2 ...
- No code modification is needed
- Other Python profilers are available, but we found this one useful

A D F A B F A B F A B

Issue of Multiple Cores I

- Let's try both single and multiple cores
- For PyTorch, we do torch.set_num_threads(1)
- An issue of the above setting is that PyTorch runs 2 threads and uses 50% CPU on each
- We can force a process to use one core by taskset -c 0 [command]

• Can we confirm that optimized BLAS is used in PyTorch?

< □ > < 同 > < 回 > < 回 > < 回 >

Some Notes on Using 217 Workstations I

- This page provides some help for students who use department workstation.
- Your home directory is unlikely to have enough storage for the embedding file and model data
- You may symlink to /tmp2/\$USER

```
mkdir -p /tmp2/$USER/runs
mkdir -p /tmp2/$USER/.vector_cache
ln -s /tmp2/$USER/runs runs
ln -s /tmp2/$USER/.vector_cache .vector_cache
```

• Be sure to read the rules of using /tmp2
