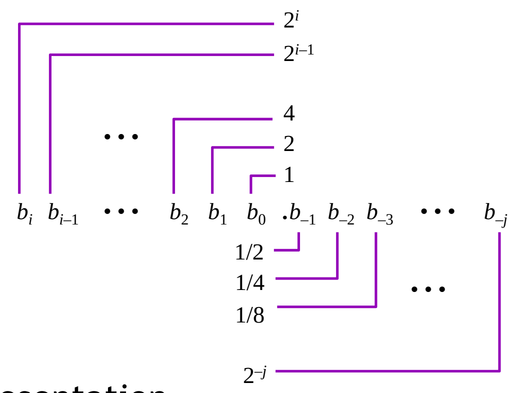
Real Arithmetic

Computer Organization and Assembly Languages

Yung-Yu Chuang

2008/12/29

Fractional binary numbers



- Representation
  - Bits to right of "binary point" represent fractional powers of 2
  - Represents rational number: $\sum_{k=-j}^{i} b_k \cdot 2^k$

Binary real numbers

- Binary real to decimal real

$$110.011_2 = 4 + 2 + 0.25 + 0.125 = 6.375$$

- Decimal real to binary real

$$\begin{aligned} 0.5625 \times 2 &= 1.125 & \text{first bit} &= 1 \\ 0.125 \times 2 &= 0.25 & \text{second bit} &= 0 \\ 0.25 \times 2 &= 0.5 & \text{third bit} &= 0 \\ 0.5 \times 2 &= 1.0 & \text{fourth bit} &= 1 \end{aligned}$$

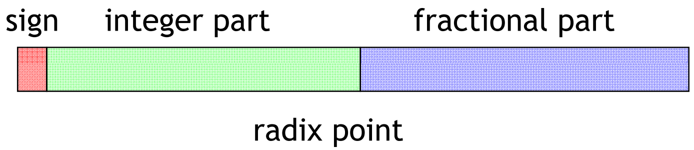
$$4.5625 = 100.1001_2$$

Fractional binary numbers examples

• Value	Representation
5-3/4	101.11_2
2-7/8	10.111_2
63/64	0.111111_2

• Value	Representation
1/3	$0.0101010101[01]..._2$
1/5	$0.001100110011[0011]..._2$
1/10	$0.0001100110011[0011]..._2$

Fixed-point numbers



0 000 0000 0000 0110 0110 0000 0000 0000 = 110.011

- only 2^{16} to 2^{-16}
  Not flexible, not adaptive to applications
- Fast computation, just integer operations.
  It is often a good way to speed up in this way
  If you know the working range beforehand.

IEEE floating point

- IEEE Standard 754
  - Established in 1985 as uniform standard for floating point arithmetic
    - Before that, many idiosyncratic formats
  - Supported by all major CPUs
- Driven by Numerical Concerns
  - Nice standards for rounding, overflow, underflow
  - Hard to make go fast
    - Numerical analysts predominated over hardware types in defining standard

IEEE floating point format

- IEEE defines two formats with different precisions: single and double

31	30 … 23	22 … 0
s	e	f

s sign bit - 0 = positive, 1 = negative
e biased exponent (8-bits) = true exponent + 7F (127 decimal). The values 00 and FF have special meaning (see text).
f fraction - the first 23-bits after the 1. in the significand.

$23.85 = 10111.11\overline{0110}_2 = 1.0111110\overline{110} \times 2^4$

$e = 127+4 = 83h$

0 100 0001 1 011 1110 1100 1100 1100 1100

IEEE floating point format

$e = 0$	and $f = 0$	denotes the number zero (which can not be normalized) Note that there is a +0 and -0.
$e = 0$	and $f \neq 0$	denotes a *denormalized number*. These are discussed in the next section.
$e = \mathrm{FF}$	and $f = 0$	denotes infinity (∞). There are both positive and negative infinities.
$e = \mathrm{FF}$	and $f \neq 0$	denotes an undefined result, known as *NaN* (Not a Number).

special values

63	62 … 52	51 … 0
s	e	f

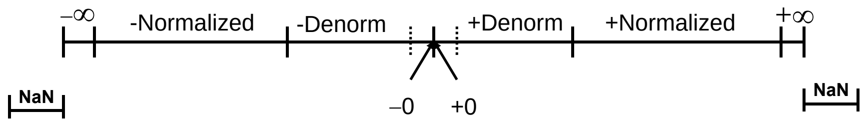
IEEE double precision

Denormalized numbers

- Number smaller than $1.0x2^{-126}$ can't be presented by a single with normalized form. However, we can represent it with denormalized format.
- $1.0000..00x2^{-126}$ the least "normalized" number
- $0.1111..11x2^{-126}$ the largest "denormalized" numbr
- $1.001x2^{-129}$=$0.001001x2^{-126}$

0 000 0000 0 001 0010 0000 0000 0000 0000

Summary of Real Number Encodings



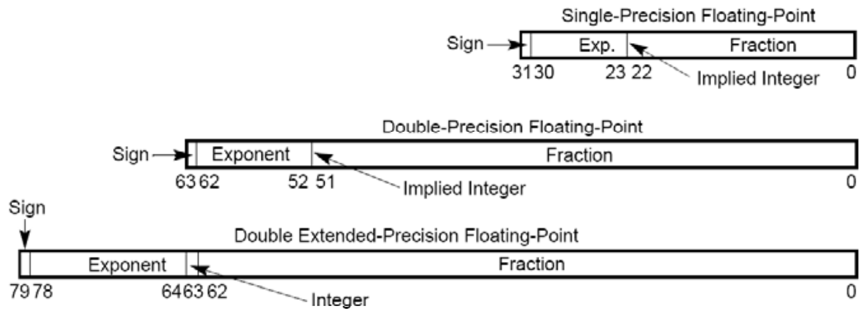
```
(3.14+1e20)-1e20=0
3.14+(1e20-1e20)=3.14
```

IA-32 floating point architecture

- Original 8086 only has integers. It is possible to simulate real arithmetic using software, but it is slow.
- 8087 floating-point processor (and 80287, 80387) was sold separately at early time.
- Since 80486, FPU (floating-point unit) was integrated into CPU.

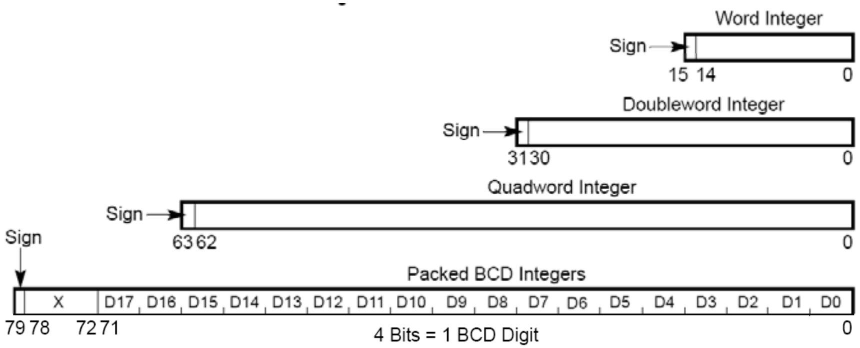
FPU data types

- Three floating-point types



FPU data types

- Four integer types

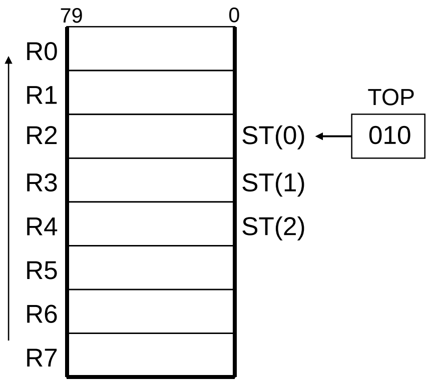


FPU registers

- Data register
- Control register
- Status register
- Tag register

Data registers

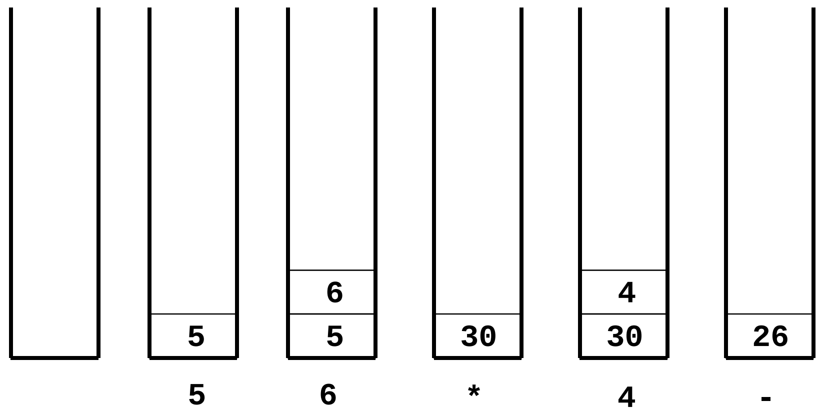
- Load: push, TOP--
- Store: pop, TOP++
- Instructions access the stack using **`ST(i)`** relative to TOP
- If TOP=0 and push, TOP wraps to R7
- If TOP=7 and pop, TOP wraps to R0
- When overwriting occurs, generate an exception



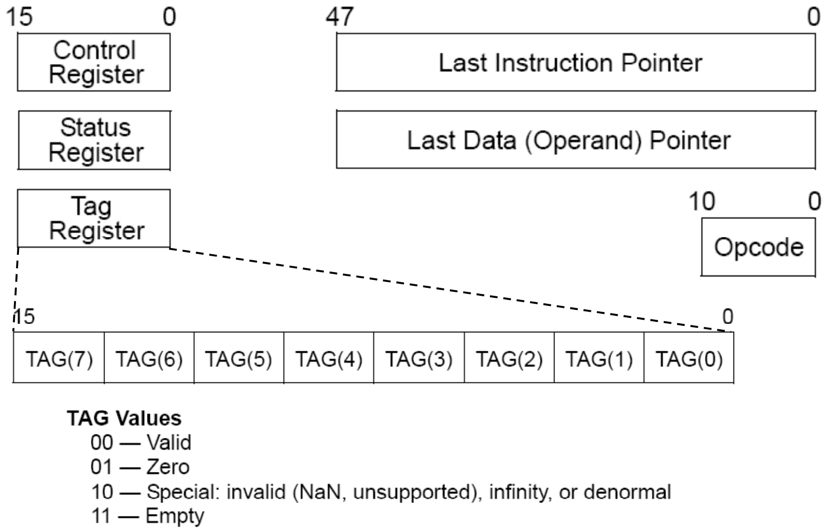
- Real values are transferred to and from memory and stored in 10-byte temporary format. When storing, convert back to integer, long, real, long real.

Postfix expression

- **`(5*6)-4`** → **`5 6 * 4 -`**

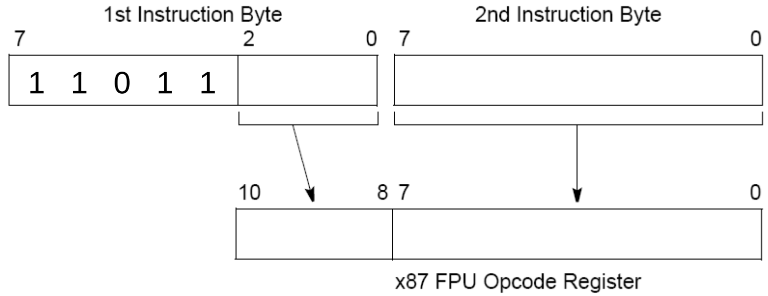


Special-purpose registers

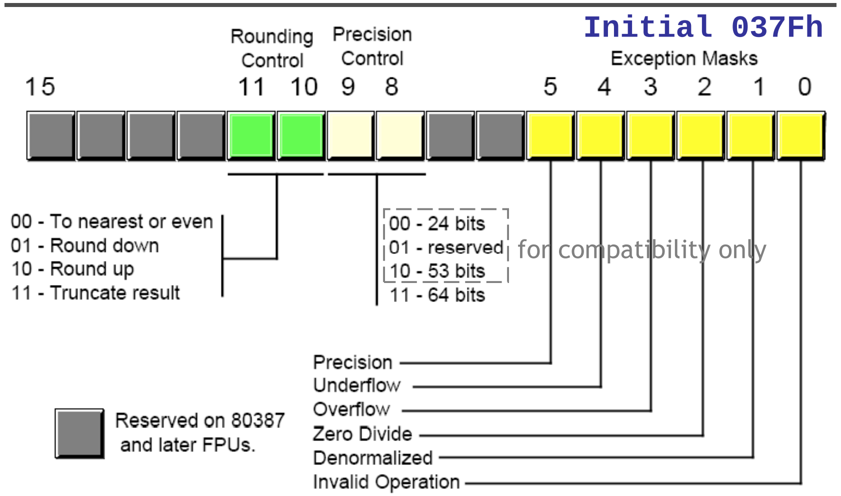


Special-purpose registers

- Last data pointer stores the memory address of the operand for the last non-control instruction. Last instruction pointer stored the address of the last non-control instruction. Both are 48 bits, 32 for offset, 16 for segment selector.



Control register



The instruction **FINIT** will initialize it to 037Fh.

Rounding

- FPU attempts to **round** an infinitely accurate result from a floating-point calculation
  - Round to nearest even: round toward to the closest one; if both are equally close, round to the even one
  - Round down: round toward to -∞
  - Round up: round toward to +∞
  - Truncate: round toward to zero
- Example
  - suppose 3 fractional bits can be stored, and a calculated value equals +1.0111.
  - rounding up by adding .0001 produces 1.100
  - rounding down by subtracting .0001 produces 1.011

Rounding

method	original value	rounded value
Round to nearest even	**1.0111**	**1.100**
Round down	**1.0111**	**1.011**
Round up	**1.0111**	**1.100**
Truncate	**1.0111**	**1.011**

method	original value	rounded value
Round to nearest even	**-1.0111**	**-1.100**
Round down	**-1.0111**	**-1.100**
Round up	**-1.0111**	**-1.011**
Truncate	**-1.0111**	**-1.011**

Floating-Point Exceptions

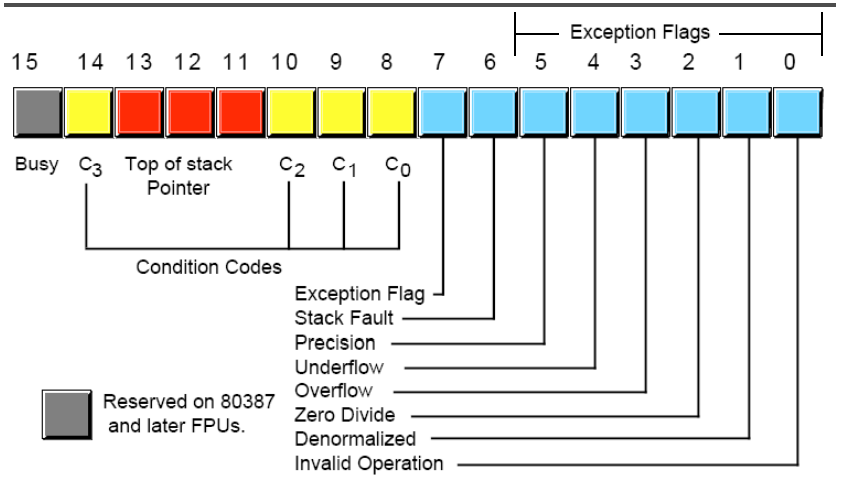
- Six types of exception conditions
  - #I: Invalid operation
  - #Z: Divide by zero
  - #D: Denormalized operand

  detect before execution

  - #O: Numeric overflow
  - #U: Numeric underflow
  - #P: Inexact precision

  detect after execution
- Each has a corresponding *mask* bit
  - if set when an exception occurs, the exception is handled automatically by FPU
  - if clear when an exception occurs, a software exception handler is invoked

Status register



C_3-C_0: condition bits after comparisons

FPU data types

```
.data
bigVal REAL10 1.212342342234234243E+864
.code
fld bigVal
```

Table 17-11 Intrinsic Data Types.

Type	Usage
QWORD	64-bit integer
TBYTE	80-bit (10-byte) integer
REAL4	32-bit (4-byte) IEEE short real
REAL8	64-bit (8-byte) IEEE long real
REAL10	80-bit (10-byte) IEEE extended real

FPU instruction set

- Instruction mnemonics begin with letter F
- Second letter identifies data type of memory operand
  - B = bcd
  - I = integer
  - no letter: floating point
- Examples
  - FBLD load binary coded decimal
  - FISTP store integer and pop stack
  - FMUL multiply floating-point operands

FPU instruction set

- **`Fop {destination}, {source}`**
- Operands
  - zero, one, or two
    - **`fadd`**
    - **`fadd [a]`**
    - **`fadd st, st(1)`**
  - no immediate operands
  - no general-purpose registers (EAX, EBX, ...) (FSTSW is the only exception which stores FPU status word to AX)
  - destination must be a stack register
  - integers must be loaded from memory onto the stack and converted to floating-point before being used in calculations

Classic stack (0-operand)

- ST(0) as source, ST(1) as destination. Result is stored at ST(1) and ST(0) is popped, leaving the result on the top. (with 0 operand, **`fadd=faddp`**)

```
fld op1                    ; op1 = 20.0
fld op2                    ; op2 = 100.0
fadd
```

	Before		After
ST(0)	100.0	ST(0)	120.0
ST(1)	20.0	ST(1)	

Memory operand (1-operand)

- ST(0) as the implied destination. The second operand is from memory.

```
FADD mySingle              ; ST(0) = ST(0) + mySingle
FSUB mySingle              ; ST(0) = ST(0) − mySingle
FSUBR mySingle             ; ST(0) = mySingle − ST(0)

FIADD myInteger            ; ST(0) = ST(0) + myInteger
FISUB myInteger            ; ST(0) = ST(0) − myInteger
FISUBR myInteger           ; ST(0) = myInteger − ST(0)
```

Register operands (2-operand)

- Register: operands are FP data registers, one must be ST.

```
FADD   st,st(1)        ; ST(0) = ST(0) + ST(1)
FDIVR  st,st(3)        ; ST(0) = ST(3) / ST(0)
FMUL   st(2),st        ; ST(2) = ST(2) * ST(0)
```

- Register pop: the same as register with a ST pop afterwards.

```
FADDP st(1),st
```

	Before		Intermediate		After
ST(0)	200.0	ST(0)	200.0	ST(0)	232.0
ST(1)	32.0	ST(1)	232.0	ST(1)	

Example: evaluating an expression

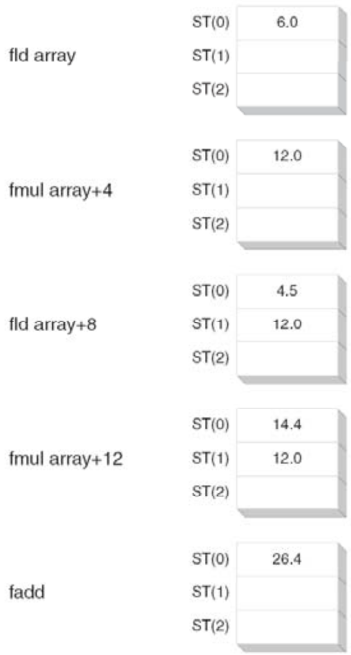
(6.0 * 2.0) + (4.5 * 3.2)

```
INCLUDE Irvine32.inc
.data
array      REAL4 6.0, 2.0, 4.5, 3.2
dotProduct REAL4 ?

.code
main PROC
   finit
   fld  array            ; push 6.0 onto the stack
   fmul array+4          ; ST(0) = 6.0 * 2.0
   fld  array+8          ; push 4.5 onto the stack
   fmul array+12         ; ST(0) = 4.5 * 3.2
   fadd                  ; ST(0) = ST(0) + ST(1)
   fstp dotProduct       ; pop stack into memory operand
   exit
main ENDP
END main
```

(6.0 * 2.0) + (4.5 * 3.2)

```
fld  array
fmul array+4
fld  array+8
fmul array+12
fadd
fstp dotProduct
```



Load

`FLD` *source*	loads a floating point number from memory onto the top of the stack. The *source* may be a single, double or extended precision number or a coprocessor register.
`FILD` *source*	reads an *integer* from memory, converts it to floating point and stores the result on top of the stack. The *source* may be either a word, double word or quad word.
`FLD1`	stores a one on the top of the stack.
`FLDZ`	stores a zero on the top of the stack.
FLDPI	stores π
FLDL2T	stores $\log_2(10)$
FLDL2E	stores $\log_2(e)$
FLDLG2	stores $\log_{10}(2)$
FLDLN2	stores $\ln(2)$

load

```
.data
array REAL8 10 DUP(?)
.code
fld array               ; direct
fld [array+16]          ; direct-offset
fld REAL8 PTR[esi]      ; indirect
fld array[esi]          ; indexed
fld array[esi*8]        ; indexed, scaled
fld REAL8 PTR[ebx+esi]; base-index
fld array[ebx+esi]      ; base-index-displacement
```

Store

FST *dest*	stores the top of the stack (ST0) into memory. The *destination* may either be a single or double precision number or a coprocessor register.
FSTP *dest*	stores the top of the stack into memory just as FST; however, after the number is stored, its value is popped from the stack. The *destination* may either a single, double or extended precision number or a coprocessor register.
FIST *dest*	stores the value of the top of the stack converted to an integer into memory. The *destination* may either a word or a double word. The stack itself is unchanged. How the floating point number is converted to an integer depends on some bits in the coprocessor's *control word*. This is a special (non-floating point) word register that controls how the coprocessor works. By default, the control word is initialized so that it rounds to the nearest integer when it converts to integer. However, the FSTCW (Store Control Word) and FLDCW (Load Control Word) instructions can be used to change this behavior.
FISTP *dest*	Same as FIST except for two things. The top of the stack is popped and the *destination* may also be a quad word.

Store

```
fst  dblOne      ; 200.0
fst  dblTwo      ; 200.0
fstp dblThree    ; 200.0
fstp dblFour     ;  32.0
```

ST(0)	200.0
ST(1)	32.0

Arithmetic instructions

Table 17-12 Basic Floating-Point Arithmetic Instructions.

FCHS	Change sign
FADD	Add source to destination
FSUB	Subtract source from destination
FSUBR	Subtract destination from source
FMUL	Multiply source by destination
FDIV	Divide destination by source
FDIVR	Divide source by destination

```
FCHS      ; change sign of ST
FABS      ; ST=|ST|
```

Floating-Point add

- FADD
  - adds source to destination
  - No-operand version pops the FPU stack after addition

```
FADD4
FADD m32fp
FADD m64fp
```

- Examples:

`fadd st(1), st(0)`

Before:	ST(1)	234.56
	ST(0)	10.1
After:	ST(1)	244.66
	ST(0)	10.1

Floating-Point subtract

- FSUB
  - subtracts source from destination.
  - No-operand version pops the FPU stack after subtracting

```
FSUB5
FSUB m32fp
FSUB m64fp
FSUB ST(0), ST(i)
FSUB ST(i), ST(0)
```

- Example:

```
fsub mySingle        ; ST -= mySingle
fsub array[edi*8]    ; ST -= array[edi*8]
```

Floating-point multiply/divide

- FMUL
  - Multiplies source by destination, stores product in destination

```
FMUL6
FMUL m32fp
FMUL m64fp
FMUL ST(0), ST(i)
FMUL ST(i), ST(0)
```

- FDIV
  - Divides destination by source, then pops the stack

```
FDIV7
FDIV m32fp
FDIV m64fp
FDIV ST(0), ST(i)
FDIV ST(i), ST(0)
```

Miscellaneous instructions

FCHS	ST0 = - ST0 Changes the sign of ST0
FABS	$ST0 = \|ST0\|$ Takes the absolute value of ST0
FSQRT	$ST0 = \sqrt{ST0}$ Takes the square root of ST0
FSCALE	$ST0 = ST0 \times 2^{\lfloor ST1 \rfloor}$ multiples ST0 by a power of 2 quickly. ST1 is not removed from the coprocessor stack.

```
.data
x    REAL4    2.75
five REAL4    5.2
.code
     fld      five     ; ST0=5.2
     fld      x        ; ST0=2.75, ST1=5.2
     fscale            ; ST0=2.75*32=88
                       ; ST1=5.2
```

Example: compute distance

```
; compute D=sqrt(x^2+y^2)
fld  x         ; load x
fld  st(0)     ; duplicate x
fmul           ; x*x

fld  y         ; load y
fld  st(0)     ; duplicate y
fmul           ; y*y

fadd           ; x*x+y*y
fsqrt
fst  D
```

Example: expression

```
; expression:valD = –valA  + (valB * valC).
.data
valA REAL8 1.5
valB REAL8 2.5
valC REAL8 3.0
valD REAL8 ?        ; will be +6.0
.code
fld valA       ; ST(0) = valA
fchs           ; change sign of ST(0)
fld  valB      ; load valB into ST(0)
fmul valC      ; ST(0) *= valC
fadd           ; ST(0) += ST(1)
fstp valD      ; store ST(0) to valD
```

Example: array sum

```
.data
N = 20
array REAL8 N DUP(1.0)
sum   REAL8 0.0
.code
     mov  ecx, N
     mov  esi, OFFSET array
     fldz                ; ST0 = 0
lp:  fadd REAL8 PTR [esi]; ST0 += *(esi)
     add  esi, 8       ; move to next double
     loop lp
     fstp sum            ; store result
```

Comparisons

`FCOM` *src*	compares `ST0` and *src*. The *src* can be a coprocessor register or a float or double in memory.
`FCOMP` *src*	compares `ST0` and *src*, then pops stack. The *src* can be a coprocessor register or a float or double in memory.
`FCOMPP`	compares `ST0` and `ST1`, then pops stack twice.
`FICOM` *src*	compares `ST0` and `(float)` *src*. The *src* can be a word or dword integer in memory.
`FICOMP` *src*	compares `ST0` and `(float)`*src*, then pops stack. The *src* can be a word or dword integer in memory.
`FTST`	compares `ST0` and 0.

Instruction	Condition Code Bits				Condition
	C3	C2	C1	C0	
fcom, fcomp, fcompp, ficom, ficomp	0	0	X	0	ST > source
	0	0	X	1	ST < source
	1	0	X	0	ST = source
	1	1	X	1	ST or source undefined
	X = Don't care				

Comparisons

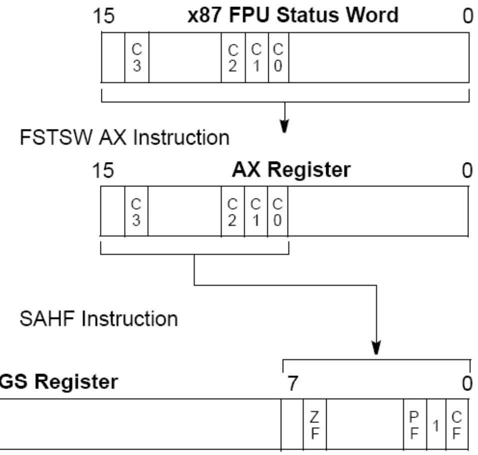
- The above instructions change FPU's status register of FPU and the following instructions are used to transfer them to CPU.

`FSTSW dest`	Stores the coprocessor status word into either a word in memory or the AX register.
`SAHF`	Stores the AH register into the FLAGS register.
`LAHF`	Loads the AH register with the bits of the FLAGS register.

- **SAHF** copies C_0 into carry, C_2 into parity and C_3 to zero. Since the sign and overflow flags are not set, use conditional jumps for unsigned integers (**ja, jae, jb, jbe, je, jz**).

Comparisons

Condition Code	Status Flag
C0	CF
C1	(none)
C2	PF
C3	ZF



Branching after FCOM

- Required steps:
  1. Use the **FSTSW** instruction to move the FPU status word into **AX**.
  2. Use the **SAHF** instruction to copy AH into the **EFLAGS** register.
  3. Use **JA, JB**, etc to do the branching.
- Pentium Pro supports two new comparison instructions that directly modify CPU's FLAGS.

```
FCOMI  ST(0), src    ; src=STn
FCOMIP ST(0), src
```

Example

```
fcomi ST(0), ST(1)
jnb   Label1
```

Example: comparison

```
.data
x  REAL8     1.0
y  REAL8     2.0
.code
     ; if (x>y) return 1 else return 0
     fld   x            ; ST0 = x
     fcomp y            ; compare ST0 and y
     fstsw ax           ; move C bits into FLAGS
     sahf
     jna   else_part    ; if x not above y, ...
then_part:
     mov   eax, 1
     jmp   end_if
else_part:
     mov   eax, 0
end_if:
```

Example: comparison

```
.data
x  REAL8     1.0
y  REAL8     2.0
.code
      ; if (x>y) return 1 else return 0
      fld   y           ; ST0 = y
      fld   x           ; ST0 = x ST1 = y
      fcomi ST(0), ST(1)

      jna   else_part   ; if x not above y, ...
then_part:
      mov   eax, 1
      jmp   end_if
else_part:
      mov   eax, 0
end_if:
```

Comparing for equality

- Not to compare floating-point values directly because of precision limit. For example,

  sqrt(2.0)*sqrt(2.0) != 2.0

instruction	FPU stack
fld two	ST(0): +2.0000000E+000
fsqrt	ST(0): +1.4142135+000
fmul ST(0), ST(0)	ST(0): +2.0000000E+000
fsub two	ST(0): +4.4408921E-016

Comparing for equality

- Calculate the absolute value of the difference between two floating-point values

```
.data
epsilon REAL8 1.0E-12    ; difference value
val2 REAL8 0.0           ; value to compare
val3 REAL8 1.001E-13     ; considered equal to val2

.code
; if( val2 == val3 ), display "Values are equal".
   fld epsilon
   fld val2
   fsub val3
   fabs
   fcomi ST(0),ST(1)
   ja skip
   mWrite <"Values are equal",0dh,0ah>
skip:
```

Example: quadratic formula

$$ax^2 + bx + c = 0 \qquad x_1, x_2 = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

```
fild    MinusFour       ; stack -4
fld     a               ; stack: a, -4
fld     c               ; stack: c, a, -4
fmulp   st1,st0         ; stack: a*c, -4
fmulp   st1,st0         ; stack: -4*a*c
fld     b
fld     b               ; stack: b, b, -4*a*c
fmulp   st1,st0         ; stack: b*b, -4*a*c
faddp   st1,st0         ; stack: b*b - 4*a*c
```

Example: quadratic formula

```
ftst                          ; test with 0
fstsw   ax
sahf
jb      no_real_solutions ; if disc < 0, no solutions
fsqrt                         ; stack: sqrt(b*b - 4*a*c)
fstp    disc                  ; store and pop stack
fld1                          ; stack: 1.0
fld     a                     ; stack: a, 1.0
fscale                        ; stack: a * 2^(1.0) = 2*a, 1
fdivp   st1,st0               ; stack: 1/(2*a)
fst     one_over_2a           ; stack: 1/(2*a)
```

$$x_1, x_2 = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Example: quadratic formula

```
fld     b                ; stack: b, 1/(2*a)
fld     disc             ; stack: disc, b, 1/(2*a)
fsubrp  st1,st0          ; stack: disc - b, 1/(2*a)
fmulp   st1,st0          ; stack: (-b + disc)/(2*a)
fstp    root1            ; store in *root1
fld     b                ; stack: b
fld     disc             ; stack: disc, b
fchs                     ; stack: -disc, b
fsubrp  st1,st0          ; stack: -disc - b
fmul    one_over_2a      ; stack: (-b - disc)/(2*a)
fstp    root2            ; store in *root2
```

$$x_1, x_2 = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$
