*with slides by Pat Hanrahan*

## Ray casting

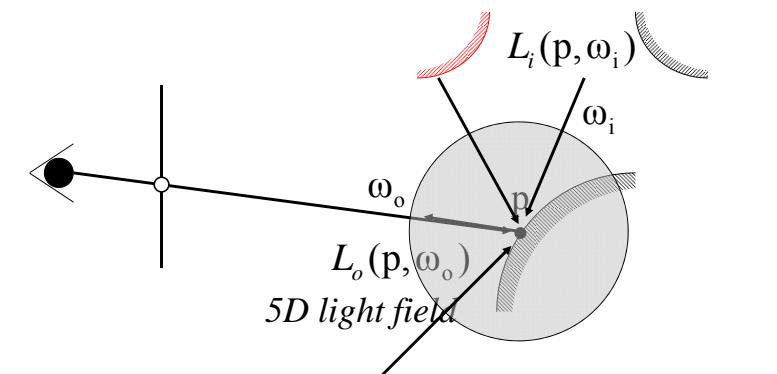

## This course

- Study of how state-of-art ray tracers work

## Rendering equation (Kajiya 1986)

$$L_o(p, \omega_o) = L_e(p, \omega_o) + \int_{S^2} f(p, \omega_o, \omega_i) L_i(p, \omega_i) |\cos \theta_i| d\omega_i$$

## Basic components

- Cameras
- Ray-object intersection
- Light distribution
- Visibility
- Surface scattering
- Recursive ray tracing
- Ray propagation (in volume)

## pbrt abstract classes (see source browser)

Table 1.1: Main Interface Types. Most of pbrt is implemented in terms of 13 key abstract base classes, listed here. Implementations of each of these can easily be added to the system to extend its functionality.

| Base class        | Directory     | Section      |
|-------------------|---------------|--------------|
| Shape             | shapes/       | 3.1          |
| Aggregate         | accelerators/ | 4.2          |
| Camera            | cameras/      | 6.1          |
| Sampler           | samplers/     | 7.2          |
| Filter            | filters/      | 7.7          |
| Film              | film/         | 7.8          |
| Material          | materials/    | 9.2          |
| Texture           | textures/     | 10.3         |
| VolumeRegion      | volumes/      | 11.3         |
| Light             | lights/       | 12.1         |
| Renderer          | renderers/    | 13.3         |
| SurfaceIntegrator | integrators/  | Ch. 15 intro |
| VolumeIntegrator  | integrators/  | 16.2         |

## pbrt

- pbrt (physically-based ray tracing) attempts to simulate physical interaction between light and matter based on ray tracing.
- Structured using object-oriented paradigm: abstract base classes are defined for important entities and their interfaces
- It is easy to extend the system. New types inherit from the appropriate base class, are compiled and linked into the system.

## Phases of execution

• **main()** in renderer/pbrt.cpp

```
int main(int argc, char *argv[]) {
    Options options;
    vector<string> filenames;
    <Process command-line arguments>
    pbrtInit(options);
    if (filename.size() == 1) {
        // Parse scene from standard input
        ParseFile("-");
    } else {
        // Parse scene from input files
        for (int i = 1; i < filenames.size(); i++)
            if (!ParseFile(filenames[i]))
                Error("Couldn't open ..., filenames[i]");
    }
    pbrtCleanup();
    return 0;
}
```

## Example scene

```

LookAt 0 10 100 0 -1 0 0 1 0
Camera "perspective" "float fov" [30]
PixelFilter "mitchell"
    "float xwidth" [2] "float ywidth" [2]
Sampler "bestcandidate"
Film "image" "string filename" ["test.exr"]
    "integer xresolution" [200]
    "integer yresolution" [200]      rendering options
# this is a meaningless comment
WorldBegin

```

```

AttributeBegin
    CoordSysTransform "camera"      "type name" [value]
    LightSource "distant"
        "point from" [0 0 0] "point to" [0 0 1]
        "color L" [3 3 3]
AttributeEnd

```

## Scene parsing (Appendix B)

- core/pbrtlex.ll and core/pbrtparse.yy
- After parsing, a **scene** object is created (core/scene.\*)

```

class scene {
    Primitive *aggregate;
    vector<Light *> lights;
    VolumeRegion *volumeRegion;
    BBox bound;
};

class aggregate {
    primitive ... primitive
    shape material
};

```

## Example scene

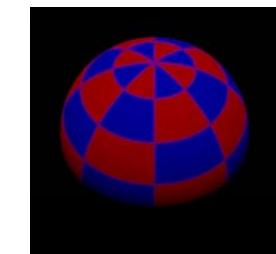

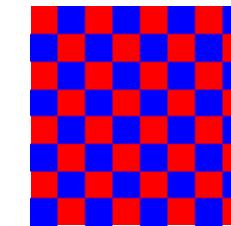

```

AttributeBegin
    Rotate 135 1 0 0

    Texture "checks" "color" "checkerboard"
        "float uscale" [8] "float vscale" [8]
        "color tex1" [1 0 0] "color tex2" [0 0 1]

    Material "matte"
        "texture Kd" "checks"
    Shape "sphere" "float radius" [20]
AttributeEnd
WorldEnd

```

## Rendering

- Rendering is handled by **Renderer** class.

```

class Renderer {
    ... given a scene, render an image or a set of measurements
    virtual void Render(Scene *scene) = 0;

    computer radiance along a ray
    virtual Spectrum Li(Scene *scn, RayDifferential &r,
for MC sampling Sample *sample, RNG &rng,
                    MemoryArena &arena, Intersection *isect,
transmittance Spectrum *T) const = 0;
    return transmittance along a ray
    virtual Spectrum Transmittance(Scene *scene,
                                    RayDifferential &ray, Sample *sample,
                                    RNG &rng, MemoryArena &arena) const = 0;
}; The later two are usually relayed to Integrator

```

## SamplerRenderer

```
class SamplerRenderer : public Renderer {  
    ...  
  
private:  
    // SamplerRenderer Private Data  
    Sampler *sampler; choose samples on image plane  
    and for integration  
  
    Camera *camera; determine lens parameters (position,  
    orientation, focus, field of view)  
    with a film  
  
    SurfaceIntegrator *surfaceIntegrator;  
    VolumeIntegrator *volumeIntegrator;  
    calculate the rendering equation  
};
```

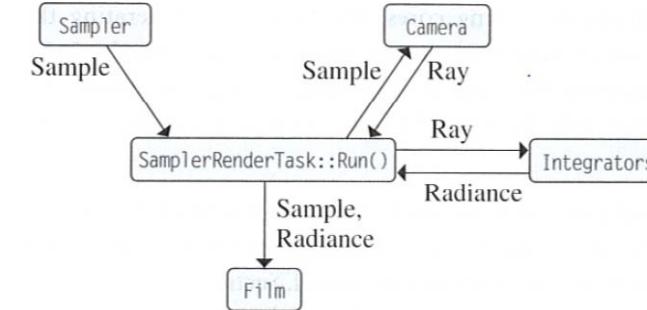

## Renderer::Render()

```
void SamplerRenderer::Render(const Scene *scene) {  
    ...  
    scene dependent initialization such photon map  
    surfaceIntegrator->Preprocess(scene,camera,this);  
    volumeIntegrator->Preprocess(scene,camera,this);  
  
    sample structure depends on types of integrators  
    Sample *sample = new Sample(sampler,  
        surfaceIntegrator, volumeIntegrator, scene);  
  
    We want many tasks to fill in the core (see histogram next page).  
    If there are too few, some core will be idle. But, threads have  
    overheads. So, we do not want too many either.  
  
    int nPixels = camera->film->xResolution  
        * camera->film->yResolution;  
    int nTasks = max(32 * NumSystemCores(), for a core  
        nPixels / (16*16)); at least 32 tasks  
    power2 easier to divide  
    nTasks = RoundUpPow2(nTasks);
```

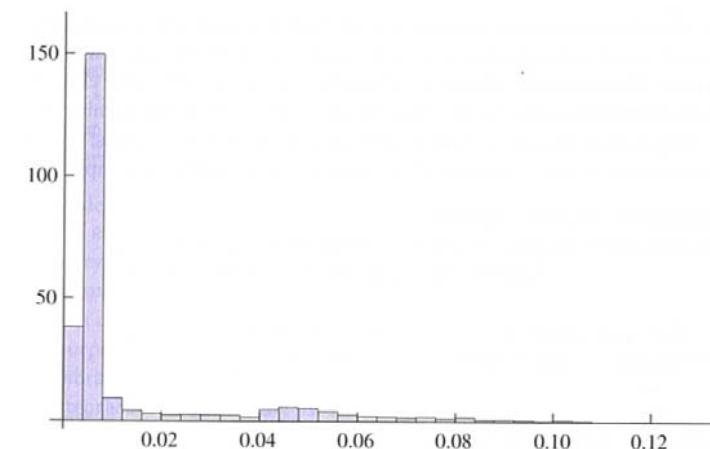

## The main rendering loop

- After **scene** and **Renderer** are constructed, **Renderer::Render()** is invoked.

## Histogram of running time

- The longest-running task took 151 times longer than the slowest.

## Renderer::Render()

```
vector<Task *> renderTasks;
for (int i = 0; i < nTasks; ++i)
    renderTasks.push_back(new SamplerRendererTask(scene, this, camera, reporter,
        sampler, sample, nTasks-1-i, nTasks));
        task id          total tasks

EnqueueTasks(renderTasks);
WaitForAllTasks();
for (int i = 0; i < renderTasks.size(); ++i)
    delete renderTasks[i];

delete sample;
camera->film->WriteImage();
}
```

## SamplerRenderTask::Run

```
for (int i = 0; i < sampleCount; ++i) {
    for vignetting
        float rayWeight = camera->GenerateRayDifferential(samples[i], &rays[i]);
                    ray differential
                    for antialiasing
    rays[i].ScaleDifferentials(
        1.f / sqrtf(sampler->samplesPerPixel));

    if (rayWeight > 0.f)
        Ls[i] = rayWeight * renderer->Li(scene, rays[i],
            &samples[i], rng, arena, &isects[i], &Ts[i]);
    else { Ls[i] = 0.f; Ts[i] = 1.f; }

    for (int i = 0; i < sampleCount; ++i)
        camera->film->AddSample(samples[i], Ls[i]);
}
```

## SamplerRenderTask::Run

- 
- When the task system decided to run a task on a particular processor, `SamplerRenderTask::Run()` will be called.

```
void SamplerRenderTask::Run() {
    // decided which part it is responsible for
    ...
    int sampleCount;
    while ((sampleCount=sampler ->GetMoreSamples(samples, rng)) > 0) {
        // Generate camera rays and compute radiance
    }
}
```

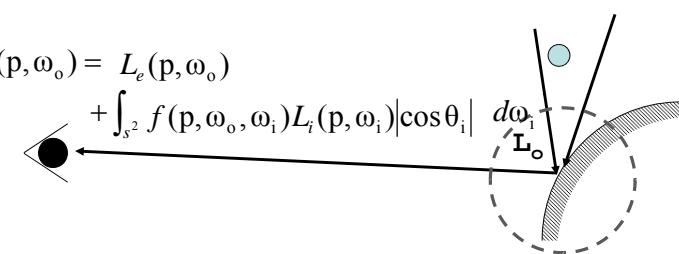

## SamplerRenderTask::Li

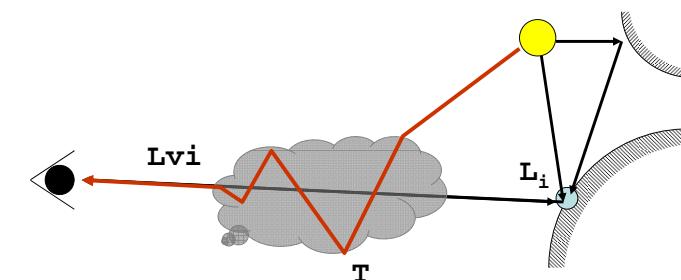

```
Spectrum SamplerRenderTask::Li(Scene *scene,
    RayDifferential &ray, Sample *sample,
    ..., Intersection *isect, Spectrum *T)
{
    Spectrum Li = 0.f;
    if (scene->Intersect(ray, isept))
        Li = surfaceIntegrator->Li(scene, this,
            ray, *isect, sample, rng, arena);
    else { // ray that doesn't hit any geometry
        for (i=0; i<scene->lights.size(); ++i)
            Li += scene->lights[i]->Le(ray);
    }
    Spectrum Lvi = volumeIntegrator->Li(scene, this,
        ray, sample, rng, T, arena);
    return *T * Li + Lvi;
}
```

## Surface integrator's Li

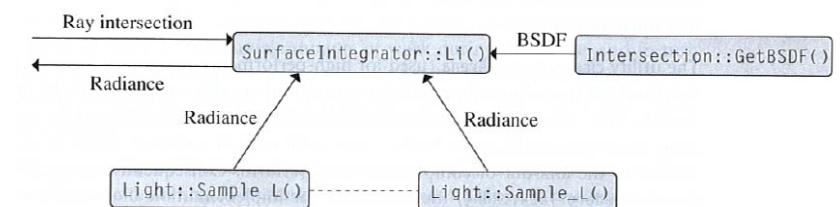

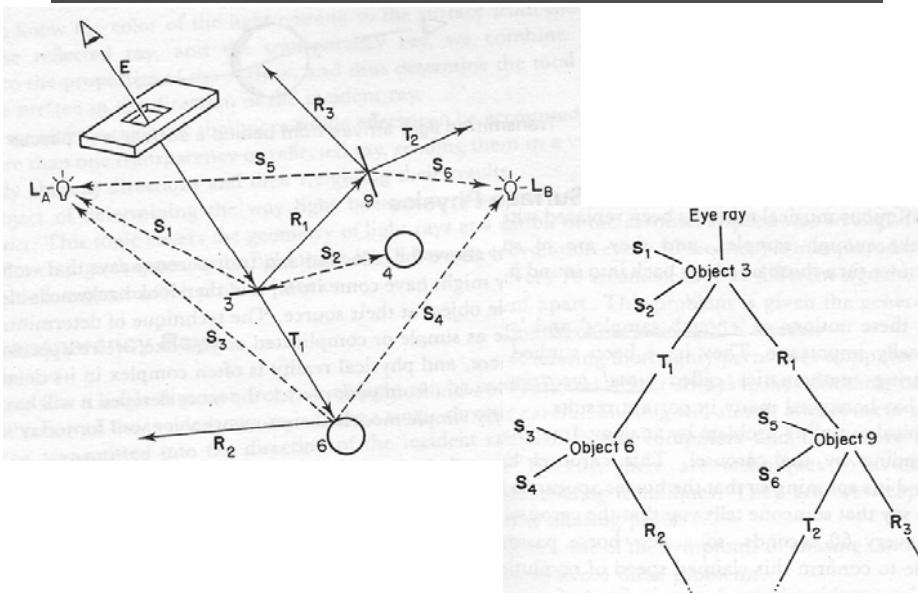

$$L_o(p, \omega_o) = L_e(p, \omega_o)$$

## SamplerRenderTask::Li

## Whitted model

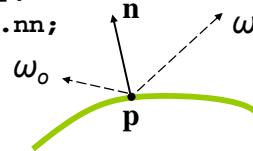

## Whitted integrator

- in integrators/whitted.cpp

```
class WhittedIntegrator:public SurfaceIntegrator
Spectrum WhittedIntegrator::Li(Scene *scene,
    Renderer *renderer, RayDifferential &ray,
    Intersection &isect, Sample *sample, RNG &rng,
    MemoryArena &arena) const
{
    BSDF *bsdf = isect.GetBSDF(ray, arena);

    //Initialize common variables for Whitted integrator
    const Point &p = bsdf->dgShading.p;
    const Normal &n = bsdf->dgShading.nn;
    Vector wo = -ray.d;
```

## Whitted integrator

```
if (ray.depth + 1 < maxDepth) {
    // Trace for specular reflection and refraction
    L += SpecularReflect(ray, bsdf, rng, isect,
        renderer, scene, sample, arena);
    L += SpecularTransmit(ray, bsdf, rng, isect,
        renderer, scene, sample, arena);
}
return L;
```

## Whitted integrator

```
// Compute emitted light if ray hits light source
L += isect.Le(wo);
// Add contribution of each light source direct lighting
for (i = 0; i < scene->lights.size(); ++i) {
    Vector wi;
    float pdf;
    VisibilityTester visibility;
    Spectrum Li = scene->lights[i]->Sample_L(p,
        isect.rayEpsilon, LightSample(rng), ray.time,
        &wi, &pdf, &visibility);
    if (Li.IsBlack() || pdf == 0.f) continue;
    Spectrum f = bsdf->f(wo, wi);
    if (!f.IsBlack() && visibility.Unoccluded(scene))
        L += f * Li * AbsDot(wi, n) *
            visibility.Transmittance(scene, renderer,
            sample, rng, arena) / pdf;
}
```

## Specular Reflectance

## Specular Reflectance

In core/integrator.cpp utility functions

```
Spectrum SpecularReflect(RayDifferential &ray,
    BSDF *bsdf, RNG &rng, const Intersection &isect,
    Renderer *renderer, Scene *scene, Sample *sample,
    MemoryArena &arena)
{
    Vector wo = -ray.d, wi;
    float pdf;
    const Point &p = bsdf->dgShading.p;
    const Normal &n = bsdf->dgShading.nn;

    Spectrum f = bsdf->Sample_f(wo, &wi,
        BSDFSample(rng), &pdf,
        BxDFType(BSDF_REFLECTION | BSDF_SPECULAR));
```

## SpecularReflect

```
Spectrum L = 0.f;
if (pdf > 0.f && !f.IsBlack()
    && AbsDot(wi, n) != 0.f) {
    <Compute ray differential _rd_ for specular
    reflection>

    Spectrum Li = renderer->Li(scene, rd, sample,
                                rng, arena);
    L = f * Li * AbsDot(wi, n) / pdf;
}
return L;
}
```

## Code optimization

- Two commonly used tips
  - Divide, square root and trigonometric are among the slowest (10-50 times slower than +\*). Multiplying 1/r for dividing r.
  - Being cache conscious

## Cache-conscious programming

- `alloca`
- `AllocAligned()`, `FreeAligned()` make sure that memory is cache-aligned

- Use union and bitfields to reduce size and increase locality
- Split data into hot and cold

## Cache-conscious programming

- Arena-based allocation allows faster allocation and better locality because of contiguous addresses.
- Blocked 2D array, used for film
