Announcements

 Project #2 was due yesterday. Send it directly to me. Please hand it in before Sunday if possible.

Structure from motion

Digital Visual Effects, Spring 2008 Yung-Yu Chuang 2008/4/22

with slides by Richard Szeliski, Steve Seitz, Zhengyou Zhang and Marc Pollefyes

Outline

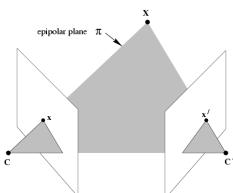

- Epipolar geometry and fundamental matrix
- Structure from motion
- Factorization method
- Bundle adjustment
- Applications

Epipolar geometry & fundamental matrix

The epipolar geometry

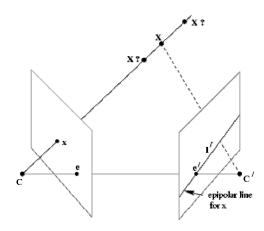

epipolar geometry demo

C,C',x,x' and X are coplanar

The epipolar geometry

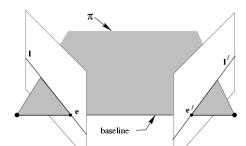

What if only C, C', x are known?

The epipolar geometry

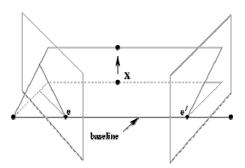

All points on π project on I and I'

The epipolar geometry

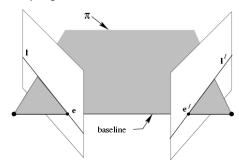

Family of planes π and lines l and l' intersect at e and e'

The epipolar geometry

epipolar pole

epipolar geometry demo

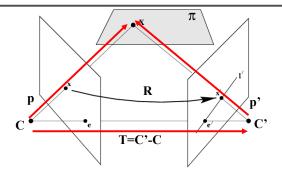

- = intersection of baseline with image plane
- = projection of projection center in other image

epipolar plane = plane containing baseline epipolar line = intersection of epipolar plane with image

The fundamental matrix F

Two reference frames are related via the extrinsic parameters

$$p' = R(p - T)$$

The equation of the epipolar plane through X is

$$(\mathbf{p} - \mathbf{T})^{\mathrm{T}} (\mathbf{T} \times \mathbf{p}) = 0 \implies (\mathbf{R}^{\mathrm{T}} \mathbf{p}')^{\mathrm{T}} (\mathbf{T} \times \mathbf{p}) = 0$$

The fundamental matrix F

$$(\mathbf{R}^{\mathrm{T}}\mathbf{p}')^{\mathrm{T}}(\mathbf{T}\times\mathbf{p}) = 0$$
$$\mathbf{T}\times\mathbf{p} = \mathbf{S}\mathbf{p}$$

$$\mathbf{S} = \begin{bmatrix} 0 & -T_z & T_y \\ T_z & 0 & -T_x \\ -T_y & T_x & 0 \end{bmatrix}$$

$$(\mathbf{R}^{\mathrm{T}}\mathbf{p}')^{\mathrm{T}}(\mathbf{S}\mathbf{p}) = 0$$

$$(\mathbf{p'}^{\mathrm{T}}\mathbf{R})(\mathbf{S}\mathbf{p}) = 0$$

$$\mathbf{p'}^{\mathsf{T}}\mathbf{E}\mathbf{p} = 0$$
 essential matrix

The fundamental matrix F

$$\mathbf{p'}^{\mathrm{T}} \mathbf{E} \mathbf{p} = 0$$

Let M and M' be the intrinsic matrices, then

$$\mathbf{p} = \mathbf{M}^{-1}\mathbf{x} \qquad \mathbf{p'} = \mathbf{M'}^{-1}\mathbf{x'}$$

$$(\mathbf{M'}^{-1}\mathbf{x'})^{\mathrm{T}}\mathbf{E}(\mathbf{M}^{-1}\mathbf{x}) = 0$$

$$\mathbf{x'}^{\mathsf{T}} \mathbf{M'}^{\mathsf{T}} \mathbf{E} \mathbf{M}^{\mathsf{T}} \mathbf{x} = 0$$

$$\mathbf{x}^{\mathsf{T}}\mathbf{F}\mathbf{x} = 0$$
 fundamental matrix

The fundamental matrix F

- **Digi**VFX
- The fundamental matrix is the algebraic representation of epipolar geometry
- The fundamental matrix satisfies the condition that for any pair of corresponding points x↔x' in the two images

$$\mathbf{x'}^{\mathsf{T}} \mathbf{F} \mathbf{x} = \mathbf{0} \qquad \left(\mathbf{x'}^{\mathsf{T}} \mathbf{l'} = \mathbf{0} \right)$$

The fundamental matrix F

Digi<mark>VFX</mark>

F is the unique 3x3 rank 2 matrix that satisfies $x'^TFx=0$ for all $x \leftrightarrow x'$

- 1. Transpose: if F is fundamental matrix for (P,P'), then F^T is fundamental matrix for (P',P)
- 2. Epipolar lines: $I' = Fx \& I = F^Tx'$
- 3. Epipoles: on all epipolar lines, thus $e'^TFx=0$, $\forall x \Rightarrow e'^TF=0$, similarly Fe=0
- 4. F has 7 d.o.f., i.e. 3x3-1(homogeneous)-1(rank2)
- 5. F is a correlation, projective mapping from a point x to a line I'=Fx (not a proper correlation, i.e. not invertible)

The fundamental matrix F

- It can be used for
 - Simplifies matching
 - Allows to detect wrong matches

Estimation of F-8-point algorithm

• The fundamental matrix F is defined by

$$\mathbf{x'}^{\mathsf{T}}\mathbf{F}\mathbf{x} = 0$$

for any pair of matches **x** and **x**' in two images.

• Let
$$\mathbf{x} = (u, v, 1)^T$$
 and $\mathbf{x}' = (u', v', 1)^T$, $\mathbf{F} = \begin{bmatrix} f_{11} & f_{12} & f_{13} \\ f_{21} & f_{22} & f_{23} \\ f_{31} & f_{32} & f_{33} \end{bmatrix}$ each match gives a linear equation

$$uu'f_{11} + vu'f_{12} + u'f_{13} + uv'f_{21} + vv'f_{22} + v'f_{23} + uf_{31} + vf_{32} + f_{33} = 0$$

8-point algorithm

$$\begin{bmatrix} u_{1}u_{1}' & v_{1}u_{1}' & u_{1}' & u_{1}v_{1}' & v_{1}v_{1}' & v_{1}' & u_{1} & v_{1} & 1\\ u_{2}u_{2}' & v_{2}u_{2}' & u_{2}' & u_{2}v_{2}' & v_{2}v_{2}' & v_{2}' & u_{2} & v_{2} & 1\\ \vdots & \vdots\\ u_{n}u_{n}' & v_{n}u_{n}' & u_{n}' & u_{n}v_{n}' & v_{n}v_{n}' & v_{n}' & u_{n} & v_{n} & 1 \end{bmatrix} \begin{bmatrix} f_{11} \\ f_{12} \\ f_{13} \\ f_{21} \\ f_{22} \\ f_{23} \\ f_{31} \\ f_{32} \\ f_{33} \end{bmatrix} = 0$$

• In reality, instead of solving $\mathbf{Af} = 0$, we seek \mathbf{f} to minimize $\|\mathbf{Af}\|$ subj. $\|\mathbf{f}\| = 1$. Find the vector corresponding to the least singular value.

8-point algorithm

- To enforce that F is of rank 2, F is replaced by F' that minimizes $\|\mathbf{F} \mathbf{F}'\|$ subject to det $\mathbf{F}' = 0$.
- It is achieved by SVD. Let $\mathbf{F} = \mathbf{U} \Sigma \mathbf{V}^{\mathrm{T}}$, where

$$\Sigma = \begin{bmatrix} \sigma_1 & 0 & 0 \\ 0 & \sigma_2 & 0 \\ 0 & 0 & \sigma_3 \end{bmatrix}, \text{ let } \Sigma' = \begin{bmatrix} \sigma_1 & 0 & 0 \\ 0 & \sigma_2 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

then $\mathbf{F'} = \mathbf{U} \mathbf{\Sigma'} \mathbf{V}^{\mathrm{T}}$ is the solution.

8-point algorithm

% Build the constraint matrix $A = \begin{bmatrix} x2(1,:)'.*x1(1,:)' & x2(1,:)'.*x1(2,:)' & x2(1,:)' & \dots \\ & x2(2,:)'.*x1(1,:)' & x2(2,:)'.*x1(2,:)' & x2(2,:)' & \dots \\ & x1(1,:)' & x1(2,:)' & ones(npts,1) \end{bmatrix};$

[U,D,V] = svd(A);

- % Extract fundamental matrix from the column of V
- % corresponding to the smallest singular value.

F = reshape(V(:,9),3,3)';

% Enforce rank2 constraint
[U,D,V] = svd(F);
F = U*diaq([D(1,1) D(2,2) 0])*V';

8-point algorithm

- Pros: it is linear, easy to implement and fast
- Cons: susceptible to noise

Problem with 8-point algorithm

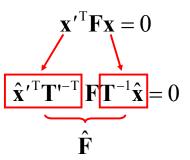

$$\begin{bmatrix} u_{1}u_{1}' & v_{1}u_{1}' & u_{1}' & u_{1}v_{1}' & v_{1}v_{1}' & v_{1}' & u_{1} & v_{1} & 1 \\ u_{2}u_{2}' & v_{2}u_{2}' & u_{2}' & u_{2}v_{2}' & v_{2}v_{2}' & v_{2}' & u_{2} & v_{2} & 1 \\ \vdots & \vdots \\ u_{n}u_{n}' & v_{n}u_{n}' & u_{n}' & u_{n}v_{n}' & v_{n}v_{n}' & v_{n}' & u_{n} & v_{n} & 1 \end{bmatrix} \begin{bmatrix} J_{11} \\ f_{12} \\ f_{13} \\ f_{21} \\ f_{22} \\ f_{23} \\ f_{31} \\ f_{32} \\ f_{33} \end{bmatrix} = 0$$
Orders of magnitude difference between column of data matrix

→ least-squares yields poor results

Normalized 8-point algorithm

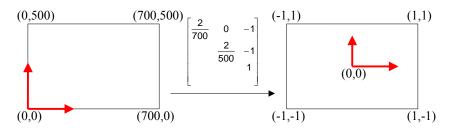

- 1. Transform input by $\hat{\mathbf{x}}_i = T\mathbf{x}_i$, $\hat{\mathbf{x}}_i' = T\mathbf{x}_i'$
- 2. Call 8-point on $\hat{\mathbf{x}}_i$, $\hat{\mathbf{x}}_i^{'}$ to obtain $\hat{\mathbf{F}}$
- 3. $\mathbf{F} = \mathbf{T}'^{\mathrm{T}} \hat{\mathbf{F}} \mathbf{T}$

Normalized 8-point algorithm

normalized least squares yields good results Transform image to $\sim[-1,1]x[-1,1]$

Normalized 8-point algorithm

Normalization

function [newpts, T] = normalise2dpts(pts)

RANSAC

repeat

select minimal sample (8 matches)

compute solution(s) for F

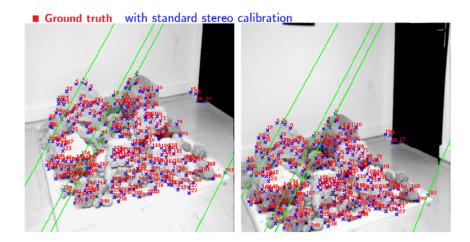

determine inliers

until $\Gamma(\#inliers, \#samples) > 95\%$ or too many times

compute F based on all inliers

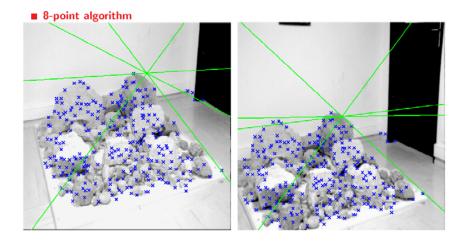

Results (ground truth)

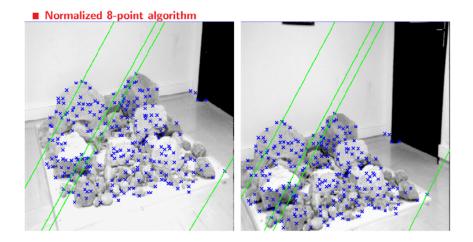

Results (8-point algorithm)

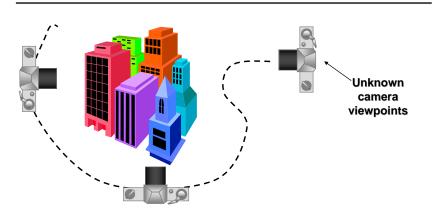

Results (normalized 8-point algorithm)

Structure from motion

Structure from motion

structure for motion: automatic recovery of <u>camera motion</u> and <u>scene structure</u> from two or more images. It is a self calibration technique and called *automatic camera tracking* or *matchmoving*.

Applications

- For computer vision, multiple-view shape reconstruction, novel view synthesis and autonomous vehicle navigation.
- For film production, seamless insertion of CGI into live-action backgrounds

Matchmove

example #1

example #3

CCRFA

- http://www.ccrfa.com/ccrfa/
- Making of "The Disappearing Act"
- 2007 winner

Structure from motion

example #2

example #4

SFM pipeline

Structure from motion

- Step 1: Track Features
 - Detect good features, Shi & Tomasi, SIFT
 - Find correspondences between frames
 - Lucas & Kanade-style motion estimation
 - · window-based correlation
 - SIFT matching

KLT tracking

http://www.ces.clemson.edu/~stb/klt/

Structure from Motion

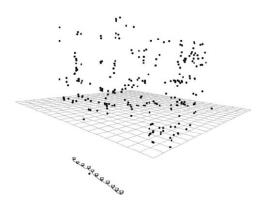

- Step 2: Estimate Motion and Structure
 - Simplified projection model, e.g., [Tomasi 92]
 - 2 or 3 views at a time [Hartley 00]

Structure from Motion

- Step 3: Refine estimates
 - "Bundle adjustment" in photogrammetry
 - Other iterative methods

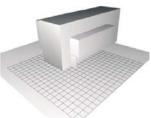

Structure from Motion

• Step 4: Recover surfaces (image-based triangulation, silhouettes, stereo...)

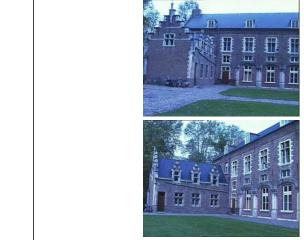

Problem statement

Notations

- n 3D points are seen in m views
- q=(u, v, 1): 2D image point
- p=(x,y,z,1): 3D scene point
- Π : projection matrix
- π : projection function
- q_{ij} is the projection of the *i*-th point on image j

Factorization methods

• λ_{ii} projective depth of q_{ij}

$$\mathbf{q}_{ij} = \pi(\Pi_j \mathbf{p}_i) \qquad \pi(x, y, z) = (x/z, y/z)$$
$$\lambda_{ij} = z$$

Structure from motion

• Estimate \prod_i and \mathbf{p}_i to minimize

$$\mathcal{E}(\mathbf{\Pi}_1, \dots, \mathbf{\Pi}_m, \mathbf{p}_1, \dots, \mathbf{p}_n) = \sum_{j=1}^m \sum_{i=1}^n w_{ij} \log P(\pi(\mathbf{\Pi}_j \mathbf{p}_i); \mathbf{q}_{ij})$$

$$w_{ij} = \begin{cases} 1 & \text{if } p_i \text{ is visible in view j} \\ 0 & \text{otherwise} \end{cases}$$

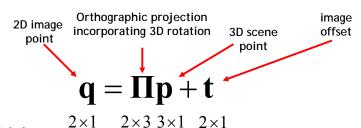

• Assume isotropic Gaussian noise, it is reduced to

$$\mathcal{E}(\mathbf{\Pi}_1, \dots, \mathbf{\Pi}_m, \mathbf{p}_1, \dots, \mathbf{p}_n) = \sum_{j=1}^m \sum_{i=1}^n w_{ij} \| \pi(\mathbf{\Pi}_j \mathbf{p}_i) - \mathbf{q}_{ij} \|^2$$

Start from a simpler projection model

SFM under orthographic projection

- Trick
 - Choose scene origin to be centroid of 3D points
 - Choose image origins to be centroid of 2D points
 - Allows us to drop the camera translation:

$$q = \Pi p$$

Factorization

- Factorization Technique
 - W is at most rank 3 (assuming no noise)
 - We can use *singular value decomposition* to factor W:

$$\mathbf{W}_{2m\times n} = \mathbf{M}' \mathbf{S}'_{2m\times 3} \mathbf{S}_{3\times n}$$

- S' differs from S by a linear transformation A:

$$W = M'S' = (MA^{-1})(AS)$$

Solve for A by enforcing metric constraints on M

factorization (Tomasi & Kanade)

projection of *n* features in one image:

$$\begin{bmatrix} \mathbf{q}_1 & \mathbf{q}_2 & \cdots & \mathbf{q}_n \end{bmatrix} = \prod_{2 \times 3} \begin{bmatrix} \mathbf{p}_1 & \mathbf{p}_2 & \cdots & \mathbf{p}_n \end{bmatrix}$$

projection of *n* features in *m* images

$$\begin{bmatrix} \mathbf{q}_{11} & \mathbf{q}_{12} & \cdots & \mathbf{q}_{1n} \\ \mathbf{q}_{21} & \mathbf{q}_{22} & \cdots & \mathbf{q}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{q}_{m1} & \mathbf{q}_{m2} & \cdots & \mathbf{q}_{mn} \end{bmatrix} = \begin{bmatrix} \mathbf{\Pi}_1 \\ \mathbf{\Pi}_2 \\ \vdots \\ \mathbf{\Pi}_m \end{bmatrix} \begin{bmatrix} \mathbf{p}_1 & \mathbf{p}_2 & \cdots & \mathbf{p}_n \end{bmatrix}$$

$$2\mathbf{m} \times \mathbf{n}$$

$$2\mathbf{m} \times 3$$

W measurement M motion

S shape

Key Observation: rank(W) <= 3

Metric constraints

• Orthographic Camera

Orthographic Camera

– Rows of
$$\Pi$$
 are orthonormal: $\Pi \Pi^{T} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

- Enforcing "Metric" Constraints
 - Compute A such that rows of M have these properties

$$M'A = M$$

Trick (not in original Tomasi/Kanade paper, but in followup work)

Constraints are linear in AAT:

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = \prod \prod^{T} = \prod' \mathbf{A} (\mathbf{A} \prod')^{T} = \prod' \mathbf{G} \prod'^{T} \qquad where \ \mathbf{G} = \mathbf{A} \mathbf{A}^{T}$$

- Solve for **G** first by writing equations for every Π_i in **M**
- Then $\mathbf{G} = \mathbf{A}\mathbf{A}^{\mathsf{T}}$ by SVD (since $\mathbf{U} = \mathbf{V}$)

Factorization with noisy data

$$\mathbf{W}_{2m\times n} = \mathbf{M}_{2m\times 3} \mathbf{S}_{3\times n} + \mathbf{E}_{2m\times n}$$

- SVD gives this solution
 - Provides optimal rank 3 approximation W' of W

$$\mathbf{W}_{2m \times n} = \mathbf{W}' + \mathbf{E}_{2m \times n}$$

- Approach
 - Estimate W', then use noise-free factorization of W' as before
 - Result minimizes the SSD between positions of image features and projection of the reconstruction

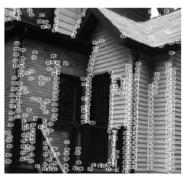

Results

Extensions to factorization methods

- Projective projection
- With missing data
- Projective projection with missing data

Bundle adjustment

Levenberg-Marquardt method

 LM can be thought of as a combination of steepest descent and the Newton method.
 When the current solution is far from the correct one, the algorithm behaves like a steepest descent method: slow, but guaranteed to converge. When the current solution is close to the correct solution, it becomes a Newton's method.

Nonlinear least square

Given a set of measurements \mathbf{x} , try to find the best parameter vector \mathbf{p} so that the squared distance $\varepsilon^T \varepsilon$ is minimal. Here, $\varepsilon = \mathbf{x} - \hat{\mathbf{x}}$, with $\hat{\mathbf{x}} = f(\mathbf{p})$.

Levenberg-Marquardt method

For a small $||\delta_{\mathbf{p}}||$, $f(\mathbf{p} + \delta_{\mathbf{p}}) \approx f(\mathbf{p}) + \mathbf{J}\delta_{\mathbf{p}}$ \mathbf{J} is the Jacobian matrix $\frac{\partial f(\mathbf{p})}{\partial \mathbf{p}}$

it is required to find the $\delta_{\mathbf{p}}$ that minimizes the quantity

This required to find the
$$b_{\mathbf{p}}$$
 that minimizes the quantity $||\mathbf{x} - f(\mathbf{p} + \delta_{\mathbf{p}})|| \approx ||\mathbf{x} - f(\mathbf{p}) - \mathbf{J}\delta_{\mathbf{p}}|| = ||\epsilon - \mathbf{J}\delta_{\mathbf{p}}||$

$$\mathbf{J}^T \mathbf{J}\delta_{\mathbf{p}} = \mathbf{J}^T \epsilon$$

$$\mathbf{N}\delta_{\mathbf{p}} = \mathbf{J}^T \epsilon$$

$$\mathbf{N}_{ii} = \mu + \left[\mathbf{J}^T \mathbf{J}\right]_{ii}$$

$$damping term$$

Levenberg-Marquardt method

- $\mu = 0$ \rightarrow Newton's method
- $\mu \rightarrow \infty$ -- steepest descent method
- Strategy for choosing μ
 - Start with some small μ
 - If error is not reduced, keep trying larger $\,\mu\,$ until it does
 - If error is reduced, accept it and reduce $\,\mu\,$ for the next iteration

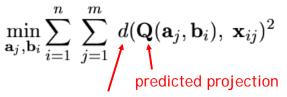

Bundle adjustment

- Digi<mark>VFX</mark>
- Bundle adjustment (BA) is a technique for simultaneously refining the 3D structure and camera parameters
- It is capable of obtaining an optimal reconstruction under certain assumptions on image error models. For zero-mean Gaussian image errors, BA is the maximum likelihood estimator.

Bundle adjustment

- n 3D points are seen in m views
- x_{ij} is the projection of the *i*-th point on image j
- a_i is the parameters for the j-th camera
- b_i is the parameters for the i-th point
- BA attempts to minimize the projection error

Euclidean distance

Bundle adjustment

Bundle adjustment

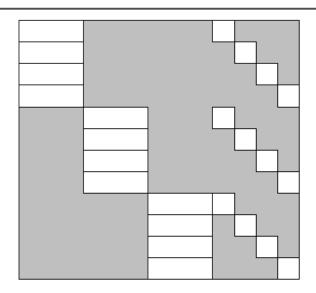

3 views and 4 points $\mathbf{P} = (\mathbf{a}_1^T, \ \mathbf{a}_2^T, \ \mathbf{a}_3^T, \ \mathbf{b}_1^T, \ \mathbf{b}_2^T, \ \mathbf{b}_3^T, \ \mathbf{b}_4^T)^T$ $\mathbf{X} = (\mathbf{x}_{11}^T, \ \mathbf{x}_{12}^T, \ \mathbf{x}_{13}^T, \ \mathbf{x}_{21}^T, \ \mathbf{x}_{22}^T, \ \mathbf{x}_{23}^T, \ \mathbf{x}_{31}^T, \ \mathbf{x}_{32}^T, \ \mathbf{x}_{33}^T, \ \mathbf{x}_{41}^T, \ \mathbf{x}_{42}^T, \ \mathbf{x}_{43}^T)^T$
