- SIFT
- Extensions
- Applications

# Features

## Features

 Also known as interesting points, salient points or keypoints. Points that you can easily point out their correspondences in multiple images using only local information.

- Distinctive: a single feature can be correctly matched with high probability.
- Invariant: invariant to scale, rotation, affine, illumination and noise for robust matching across a substantial range of affine distortion, viewpoint change and so on. That is, it is repeatable.

# Applications

- Object or scene recognition
- Structure from motion
- Stereo
- Motion tracking
- •

- Feature detection locates where they are
- Feature description describes what they are
- Feature matching decides whether two are the same one

# Harris corner detector

- We should easily recognize the point by looking through a small window
- Shifting a window in *any direction* should give *a large change* in intensity

#### flat

#### flat

flat

Change of intensity for the shift [*u*, *v*]:

Four shifts: (u,v) = (1,0), (1,1), (0,1), (-1, 1)Look for local maxima in  $min\{E\}$ 

- Noisy response due to a binary window function
- Only a set of shifts at every 45 degree is considered
- Only minimum of E is taken into account
- ⇒ Harris corner detector (1988) solves these problems.

Noisy response due to a binary window function ➤ Use a Gaussian function

$$w(x, y) = \exp\left(-\frac{(x^2 + y^2)}{2\sigma^2}\right)$$

Gaussian

Only a set of shifts at every 45 degree is considered > Consider all small shifts by Taylor's expansion

Only a set of shifts at every 45 degree is considered ➤ Consider all small shifts by Taylor's expansion

$$E(u,v) = \sum_{x,y} w(x,y) [I(x+u,y+v) - I(x,y)]^2$$
  
=  $\sum_{x,y} w(x,y) [I_x u + I_y v + O(u^2,v^2)]^2$ 

$$E(u,v) = Au^2 + 2Cuv + Bv^2$$

$$A = \sum_{x,y} w(x, y) I_x^2(x, y)$$
$$B = \sum w(x, y) I_y^2(x, y)$$

x, y

$$C = \sum_{x,y} w(x,y) I_x(x,y) I_y(x,y)$$

Equivalently, for small shifts [*u*, *v*] we have a *bilinear* approximation:

$$E(u,v) \cong \begin{bmatrix} u & v \end{bmatrix} \mathbf{M} \begin{bmatrix} u \\ v \end{bmatrix}$$

, where  $\mathbf{M}$  is a 2×2 matrix computed from image derivatives:

$$\mathbf{M} = \sum_{x,y} w(x,y) \begin{bmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{bmatrix}$$

$$E(\mathbf{u}) = \sum_{\mathbf{x}_0 \in W(\mathbf{p})} W(\mathbf{x}_0) | I(\mathbf{x}_0 + \mathbf{u}) - I(\mathbf{x}_0)|^2$$
$$|I(\mathbf{x}_0 + \mathbf{u}) - I(\mathbf{x}_0)|^2$$
$$= \left| \left( I_0 + \frac{\partial I}{\partial \mathbf{x}}^T \mathbf{u} \right) - I_0 \right|^2$$
$$= \left| \frac{\partial I}{\partial \mathbf{x}}^T \mathbf{u} \right|^2$$
$$= \mathbf{u}^T \frac{\partial I}{\partial \mathbf{x}} \frac{\partial I}{\partial \mathbf{x}}^T \mathbf{u}$$
$$= \mathbf{u}^T \mathbf{M} \mathbf{u}$$

Only minimum of *E* is taken into account

➤A new corner measurement by investigating the shape of the error function

 $\mathbf{u}^T \mathbf{M} \mathbf{u}$  represents a quadratic function; Thus, we can analyze E's shape by looking at the property of  $\mathbf{M}$ 

High-level idea: what shape of the error function will we prefer for features?

 Quadratic form (homogeneous polynomial of degree two) of *n* variables x<sub>i</sub>

$$\sum_{\substack{i=1\\i\leq j}}^{n}\sum_{j=1}^{n}c_{ij}x_{i}x_{j}$$

• Examples

$$4x_1^2 + 5x_2^2 + 3x_3^2 + 2x_1x_2 + 4x_1x_3 + 6x_2x_3$$
  
=  $\begin{pmatrix} x_1 & x_2 & x_3 \end{pmatrix} \begin{pmatrix} 4 & 1 & 2 \\ 1 & 5 & 3 \\ 2 & 3 & 3 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix}$ 

## Symmetric matrices

Quadratic forms can be represented by a real

symmetric matrix A where  $a_{ij} = \begin{cases} c_{ij} & \text{if } i = j, \\ \frac{1}{2}c_{ij} & \text{if } i < j, \\ \frac{1}{2}c_{ij} & \text{if } i < j, \\ \frac{1}{2}c_{ji} & \text{if } i > j. \end{cases}$   $\sum_{i=1}^{n} \sum_{j=1}^{n} c_{ij}x_ix_j = \sum_{i=1}^{n} \sum_{j=1}^{n} a_{ij}x_ix_j$  $= (x_1 \dots x_n) \begin{pmatrix} a_{11} \dots a_{1n} \\ \vdots & \vdots \\ a_{n1} \dots & a_{nn} \end{pmatrix} \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}$  $= \mathbf{x}^t A \mathbf{x}$  $i \leq j$ 

Eigenvalues of symmetric matrices

suppose  $A \in \mathbf{R}^{n \times n}$  is symmetric, *i.e.*,  $A = A^T$ fact: the eigenvalues of A are real

suppose 
$$Av = \lambda v, v \neq 0, v \in \mathbb{C}^{n}$$
  
 $\overline{v}^{T}Av = \overline{v}^{T}(Av) = \lambda \overline{v}^{T}v = \lambda \sum_{i=1}^{n} |v_{i}|^{2}$   
 $\overline{v}^{T}Av = \overline{(Av)}^{T}v = \overline{(\lambda v)}^{T}v = \overline{\lambda} \sum_{i=1}^{n} |v_{i}|^{2}$   
we have  $\lambda = \overline{\lambda}, i.e., \lambda \in \mathbb{R}$   
(hence, can assume  $v \in \mathbb{R}^{n}$ )

Brad Osgood

Eigenvectors of symmetric matrices

suppose  $A \in \mathbf{R}^{n \times n}$  is symmetric, *i.e.*,  $A = A^T$ fact: there is a set of orthonormal eigenvectors of A $A = Q \Lambda Q^T$  Eigenvectors of symmetric matrices

suppose  $A \in \mathbf{R}^{n \times n}$  is symmetric, *i.e.*,  $A = A^T$ **fact:** there is a set of orthonormal eigenvectors of A

$$A = Q\Lambda Q^T$$
$$\mathbf{x}^{\mathsf{T}} \mathbf{A} \mathbf{x}$$

$$= \mathbf{x}^{\mathrm{T}} \mathbf{Q} \ \mathbf{\Lambda} \ \mathbf{Q}^{\mathrm{T}} \mathbf{x}$$
$$= (\mathbf{Q}^{\mathrm{T}} \mathbf{x})^{\mathrm{T}} \ \mathbf{\Lambda} (\mathbf{Q}^{\mathrm{T}} \mathbf{x})$$
$$= \mathbf{y}^{\mathrm{T}} \ \mathbf{\Lambda} \mathbf{y}$$
$$= (\mathbf{\Lambda}^{\frac{1}{2}} \mathbf{y})^{\mathrm{T}} (\mathbf{\Lambda}^{\frac{1}{2}} \mathbf{y})$$
$$= \mathbf{z}^{\mathrm{T}} \mathbf{z}$$

Intensity change in shifting window: eigenvalue analysis

$$E(u, v) \cong \begin{bmatrix} u, v \end{bmatrix} \mathbf{M} \begin{bmatrix} u \\ v \end{bmatrix} \qquad \lambda_1, \lambda_2 - \text{eigenvalues of } \mathbf{M}$$
  
Ellipse  $E(u, v) = \text{const}$  direction of the fastest change direction of the slowest change

## Visualize quadratic functions

$$\mathbf{A} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}^T$$

## Visualize quadratic functions

$$\mathbf{A} = \begin{bmatrix} 4 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 4 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}^T$$

$$\mathbf{A} = \begin{bmatrix} 7.75 & 3.90 \\ 3.90 & 3.25 \end{bmatrix} = \begin{bmatrix} 0.50 & -0.87 \\ -0.87 & -0.50 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 10 \end{bmatrix} \begin{bmatrix} 0.50 & -0.87 \\ -0.87 & -0.50 \end{bmatrix}^T$$

## Harris corner detector

$$\lambda = \frac{a_{00} + a_{11} \pm \sqrt{\left(a_{00} - a_{11}\right)^2 + 4a_{10}a_{01}}}{2}$$

Only for reference, you do not need them to compute R

Measure of corner response:

$$R = \det \mathbf{M} - k (\operatorname{trace} \mathbf{M})^2$$

det 
$$\mathbf{M} = \lambda_1 \lambda_2$$
  
trace  $\mathbf{M} = \lambda_1 + \lambda_2$ 

(k - empirical constant, k = 0.04-0.06)

## Another view

#### Another view

#### Another view

1. Compute x and y derivatives of image

$$I_x = G_\sigma^x * I \qquad I_y = G_\sigma^y * I$$

2. Compute products of derivatives at every pixel

$$I_{x^2} = I_x \cdot I_x \qquad I_{y^2} = I_y \cdot I_y \qquad I_{xy} = I_x \cdot I_y$$

3. Compute the sums of the products of derivatives at each pixel

$$S_{x^2} = G_{\sigma'} * I_{x^2}$$
  $S_{y^2} = G_{\sigma'} * I_{y^2}$   $S_{xy} = G_{\sigma'} * I_{xy}$ 

4. Define the matrix at each pixel

$$M(x, y) = \begin{bmatrix} S_{x^{2}}(x, y) & S_{xy}(x, y) \\ S_{xy}(x, y) & S_{y^{2}}(x, y) \end{bmatrix}$$

- 5. Compute the response of the detector at each pixel  $R = \det M - k(\operatorname{trace} M)^2$
- 6. Threshold on value of R; compute nonmax suppression.

## Harris corner detector (input)

# Corner response R

#### Threshold on R

# Local maximum of R

#### Harris corner detector

 Average intensity change in direction [*u*, *v*] can be expressed as a bilinear form:

$$E(u,v) \cong \begin{bmatrix} u,v \end{bmatrix} \mathbf{M} \begin{bmatrix} u\\v \end{bmatrix}$$

• Describe a point in terms of eigenvalues of *M*: *measure of corner response* 

$$R = \lambda_1 \lambda_2 - k (\lambda_1 + \lambda_2)^2$$

• A good (corner) point should have a *large intensity change* in *all directions*, i.e. *R* should be large positive

- But, how to match them?
- What is the descriptor for a feature? The simplest solution is the intensities of its spatial neighbors. This might not be robust to brightness change or small shift/rotation.

Harris detector: some properties

• Partial invariance to *affine intensity* change

✓ Only derivatives are used => invariance to intensity shift  $I \rightarrow I + b$ 

✓ Intensity scale:  $I \rightarrow a I$ 

# Harris Detector: Some Properties

• Rotation invariance

Ellipse rotates but its shape (i.e. eigenvalues) remains the same

Corner response R is invariant to image rotation

# Harris Detector is rotation invariant

• But: not invariant to *image scale*!

All points will be classified as edges

Corner !

## Harris detector: some properties

Quality of Harris detector for different scale changes

- Consider regions (e.g. circles) of different sizes around a point
- Regions of corresponding sizes will look the same in both images

- The problem: how do we choose corresponding circles *independently* in each image?
- Aperture problem

# SIFT (Scale Invariant Feature Transform)

# SIFT

• SIFT is an carefully designed procedure with empirically determined parameters for the invariant and distinctive features.

detector

descriptor

#### SIFT stages:

- Scale-space extrema detection
- Keypoint localization
- Orientation assignment
- Keypoint descriptor

A 500x500 image gives about 2000 features

# 1. Detection of scale-space extrema

- For scale invariance, search for stable features across all possible scales using a continuous function of scale, scale space.
- SIFT uses DoG filter for scale space because it is efficient and as stable as scale-normalized Laplacian of Gaussian.

Convolution with a variable-scale Gaussian

$$L(x, y, \sigma) = G(x, y, \sigma) * I(x, y),$$
  
$$G(x, y, \sigma) = 1/(2\pi\sigma^2) \exp^{-(x^2 + y^2)/\sigma^2}$$

Difference-of-Gaussian (DoG) filter

$$G(x,y,k\sigma)-G(x,y,\sigma)$$

Convolution with the DoG filter

$$D(x, y, \sigma) = (G(x, y, k\sigma) - G(x, y, \sigma)) * I(x, y)$$
  
=  $L(x, y, k\sigma) - L(x, y, \sigma).$ 

#### Scale space

# Detection of scale-space extrema

## **Keypoint localization**

X is selected if it is larger or smaller than all 26 neighbors

- It is impossible to sample the whole space, tradeoff efficiency with completeness.
- Decide the best sampling frequency by experimenting on 32 real image subject to synthetic transformations. (rotation, scaling, affine stretch, brightness and contrast change, adding noise...)

s=3 is the best, for larger s, too many unstable features

### Pre-smoothing

 $\sigma$  =1.6, plus a double expansion

# 2. Accurate keypoint localization

- Reject points with low contrast (flat) and poorly localized along an edge (edge)
- Fit a 3D quadratic function for sub-pixel maxima

# 2. Accurate keypoint localization

- Reject points with low contrast (flat) and poorly localized along an edge (edge)
- Fit a 3D quadratic function for sub-pixel maxima  $6\frac{1}{3}$  $f(x) \approx f(0) + f'(0)x + \frac{f''(0)}{2}x^2$ 6 5  $f(x) \approx 6 + 2x + \frac{-6}{2}x^2 = 6 + 2x - 3x^2$  $f'(x) = 2 - 6x = 0 \longrightarrow \hat{x} = \frac{1}{3}$  $f(\hat{x}) = 6 + 2 \cdot \frac{1}{3} - 3 \cdot \left(\frac{1}{3}\right)^2 = 6\frac{1}{3}$  $0 \ 1$ +1/-1

# 2. Accurate keypoint localization

• Taylor series of several variables

$$T(x_1,\cdots,x_d) = \sum_{n_1=0}^{\infty}\cdots\sum_{n_d=0}^{\infty}\frac{\partial^{n_1}}{\partial x_1^{n_1}}\cdots\frac{\partial^{n_d}}{\partial x_d^{n_d}}\frac{f(a_1,\cdots,a_d)}{n_1!\cdots n_d!}(x_1-a_1)^{n_1}\cdots(x_d-a_d)^{n_d}$$

• Two variables

$$f(x, y) \approx f(0,0) + \left(\frac{\partial f}{\partial x}x + \frac{\partial f}{\partial y}y\right) + \frac{1}{2} \left(\frac{\partial^2 f}{\partial x \partial x}x^2 + 2\frac{\partial^2 f}{\partial x \partial y}xy + \frac{\partial^2 f}{\partial y \partial y}y^2\right)$$
$$f\left(\begin{bmatrix}x\\y\end{bmatrix}\right) \approx f\left(\begin{bmatrix}0\\0\end{bmatrix}\right) + \left[\frac{\partial f}{\partial x} \quad \frac{\partial f}{\partial y}\end{bmatrix}\begin{bmatrix}x\\y\end{bmatrix} + \frac{1}{2}\begin{bmatrix}x \quad y\end{bmatrix} \left[\frac{\partial^2 f}{\partial x \partial x} \quad \frac{\partial^2 f}{\partial x \partial y}\\ \frac{\partial^2 f}{\partial x \partial y} \quad \frac{\partial^2 f}{\partial y \partial y}\end{bmatrix}\begin{bmatrix}x\\y\end{bmatrix}$$
$$f(\mathbf{x}) \approx f(\mathbf{0}) + \frac{\partial f}{\partial \mathbf{x}}^T \mathbf{x} + \frac{1}{2}\mathbf{x}^T \frac{\partial^2 f}{\partial \mathbf{x}^2} \mathbf{x}$$

• Taylor expansion in a matrix form, **x** is a vector, f maps **x** to a scalar

$f(\mathbf{x}) =$	$= f + \frac{\partial f^T}{\partial \mathbf{x}}$	$\mathbf{x} + \frac{1}{2}\mathbf{x}^T \frac{\partial}{\partial t}$	$\frac{\partial^2 f}{\partial \mathbf{x}^2} \mathbf{x}$ (		an matrix symmetri

- x is a 3-vector
- Change sample point if offset is larger than 0.5
- Throw out low contrast (<0.03)

• Throw out low contrast  $|D(\hat{\mathbf{x}})| < 0.03$  $D(\hat{\mathbf{x}}) = D + \frac{\partial D}{\partial \mathbf{x}} \hat{\mathbf{x}} + \frac{1}{2} \hat{\mathbf{x}}^T \frac{\partial^2 D}{\partial \mathbf{x}^2} \hat{\mathbf{x}}$  $= D + \frac{\partial D}{\partial \mathbf{x}}^{T} \, \hat{\mathbf{x}} + \frac{1}{2} \left( -\frac{\partial^{2} D}{\partial \mathbf{x}^{2}}^{-1} \, \frac{\partial D}{\partial \mathbf{x}} \right)^{T} \frac{\partial^{2} D}{\partial \mathbf{x}^{2}} \left( -\frac{\partial^{2} D}{\partial \mathbf{x}^{2}}^{-1} \, \frac{\partial D}{\partial \mathbf{x}} \right)$  $= D + \frac{\partial D}{\partial \mathbf{x}}^{T} \, \hat{\mathbf{x}} + \frac{1}{2} \frac{\partial D}{\partial \mathbf{x}}^{T} \, \frac{\partial^{2} D}{\partial \mathbf{x}^{2}}^{-T} \frac{\partial^{2} D}{\partial \mathbf{x}^{2}} \frac{\partial^{2} D}{\partial \mathbf{x}^{2}}^{-1} \frac{\partial D}{\partial \mathbf{x}}$  $= D + \frac{\partial D}{\partial \mathbf{x}}^T \, \hat{\mathbf{x}} + \frac{1}{2} \frac{\partial D}{\partial \mathbf{x}}^T \, \frac{\partial^2 D}{\partial \mathbf{x}^2}^{-1} \frac{\partial D}{\partial \mathbf{x}}$  $= D + \frac{\partial D}{\partial \mathbf{x}}^T \,\hat{\mathbf{x}} + \frac{1}{2} \frac{\partial D}{\partial \mathbf{x}}^T \,(-\hat{\mathbf{x}})$  $= D + \frac{1}{2} \frac{\partial D^{T}}{\partial t} \hat{\mathbf{x}}$ 

$$\mathbf{H} = \begin{bmatrix} D_{xx} & D_{xy} \\ D_{xy} & D_{yy} \end{bmatrix}$$
 Hessian matrix at keypoint location

$$Tr(\mathbf{H}) = D_{xx} + D_{yy} = \alpha + \beta,$$
$$Det(\mathbf{H}) = D_{xx}D_{yy} - (D_{xy})^2 = \alpha\beta.$$

Let 
$$\alpha = r\beta$$
  $\frac{\text{Tr}(\mathbf{H})^2}{\text{Det}(\mathbf{H})} = \frac{(\alpha + \beta)^2}{\alpha\beta} = \frac{(r\beta + \beta)^2}{r\beta^2} = \frac{(r+1)^2}{r}$ 

Keep the points with 
$$\frac{\text{Tr}(\mathbf{H})^2}{\text{Det}(\mathbf{H})} < \frac{(r+1)^2}{r}$$
. r=10

#### Maxima in D

#### Remove low contrast and edges

#### **Keypoint detector**

- By assigning a consistent orientation, the keypoint descriptor can be orientation invariant.
- For a keypoint, L is the Gaussian-smoothed image with the closest scale,

$$m(x,y) = \sqrt{(L(x+1,y) - L(x-1,y))^2 + (L(x,y+1) - L(x,y-1))^2}$$

•Keypoint location = extrema location
•Keypoint scale is scale of the DOG image

gradient magnitude weighted by 2D gaussian kernel

σ=1.5\*scale of the keypoint

weighted gradient magnitude

There may be multiple orientations.

# accurate peak position is determined by fitting

In this case, generate duplicate keypoints, one with orientation at 25 degrees, one at 155 degrees.

Design decision: you may want to limit number of possible multiple peaks to two.

 $0 + 2\pi$ 

36-bin orientation histogram over 360°, weighted by m and 1.5\*scale falloff
Peak is the orientation
Local peak within 80% creates multiple orientations
About 15% has multiple orientations

and they contribute a lot to stability

#### SIFT descriptor

## 4. Local image descriptor

- Thresholded image gradients are sampled over 16x16 array of locations in scale space
- Create array of orientation histograms (w.r.t. key orientation)
- 8 orientations x 4x4 histogram array = 128 dimensions
- Normalized, clip values larger than 0.2, renormalize

 for a feature x, he found the closest feature x<sub>1</sub> and the second closest feature x<sub>2</sub>. If the distance ratio of d(x, x<sub>1</sub>) and d(x, x<sub>1</sub>) is smaller than 0.8, then it is accepted as a match.

#### SIFT flow

#### Maxima in D

#### Remove low contrast

#### Remove edges

#### SIFT descriptor

Computed affine transformation from rotated image to original image:

0.7060 -0.7052 128.4230

- 0.7057 0.7100 -128.9491
  - 0 0 1.0000
- Actual transformation from rotated image to original image:

0.7071 -0.7071 128.6934

- 0.7071 0.7071 -128.6934
  - 0 0 1.0000

# **SIFT** extensions

Average face:

Top ten eigenfaces (left = highest eigenvalue, right = lowest eigenvalue):

#### PCA-SIFT

- Only change step 4
- Pre-compute an eigen-space for local gradient patches of size 41x41
- 2x39x39=3042 elements
- Only keep 20 components
- A more compact descriptor
# GLOH (Gradient location-orientation histogram)

17 location bins16 orientation binsAnalyze the 17x16=272-deigen-space, keep 128 components

SIFT is still considered the best.

# **Multi-Scale Oriented Patches**

- Simpler than SIFT. Designed for image matching. [Brown, Szeliski, Winder, CVPR'2005]
- Feature detector
  - Multi-scale Harris corners
  - Orientation from blurred gradient
  - Geometrically invariant to rotation
- Feature descriptor
  - Bias/gain normalized sampling of local patch (8x8)
  - Photometrically invariant to affine changes in intensity

$$P_0(x,y) = I(x,y)$$

$$P_l(x,y) = P_l(x,y) * g_{\sigma_p}(x,y)$$

$$P_{l+1}(x,y) = P_l'(sx,sy)$$

$$s = 2 \quad \sigma_p = 1.0$$
Level n: 2<sup>n</sup> x2<sup>n</sup>

 Image stitching is mostly concerned with matching images that have the same scale, so sub-octave pyramid might not be necessary.

$$\mathbf{H}_{l}(x,y) = \nabla_{\sigma_{d}} P_{l}(x,y) \nabla_{\sigma_{d}} P_{l}(x,y)^{T} * g_{\sigma_{i}}(x,y)$$

$$abla_{\sigma} f(x, y) \triangleq \nabla f(x, y) * g_{\sigma}(x, y)$$
smoother version of gradients

$$\sigma_i = 1.5 \qquad \sigma_d = 1.0$$

Corner detection function:

$$f_{HM}(x,y) = \frac{\det \mathbf{H}_l(x,y)}{\operatorname{tr} \mathbf{H}_l(x,y)} = \frac{\lambda_1 \lambda_2}{\lambda_1 + \lambda_2}$$

Pick local maxima of 3x3 and larger than 10

### **Keypoint detection function**

- Restrict the maximal number of interest points, but also want them spatially well distributed
- Only retain maximums in a neighborhood of radius *r*.
- Sort them by strength, decreasing *r* from infinity until the number of keypoints (500) is satisfied.

#### Non-maximal suppression

(a) Strongest 250

(b) Strongest 500

(c) ANMS 250, r = 24

(d) ANMS 500, r=16

#### Sub-pixel refinement

$$f(\mathbf{x}) = f + \frac{\partial f}{\partial \mathbf{x}}^T \mathbf{x} + \frac{1}{2} \mathbf{x}^T \frac{\partial^2 f}{\partial \mathbf{x}^2} \mathbf{x}$$
$$\mathbf{x}_m = -\frac{\partial^2 f}{\partial \mathbf{x}^2}^{-1} \frac{\partial f}{\partial \mathbf{x}}$$
$$\frac{\frac{\partial f}{\partial \mathbf{x}}}{\frac{f_{-1,1} \quad f_{0,1} \quad f_{1,1}}{f_{-1,0} \quad f_{0,0} \quad f_{1,0}}}{\frac{f_{-1,-1} \quad f_{0,-1} \quad f_{1,-1}}{f_{-1,-1} \quad f_{0,-1} \quad f_{1,-1}}} \xrightarrow{\frac{\partial^2 f}{\partial \mathbf{x}^2}} = \frac{f_{1,0} - 2f_{0,0} + f_{-1,0}}{\frac{\partial^2 f}{\partial \mathbf{y}^2}} = f_{0,1} - 2f_{0,0} + f_{0,-1}}$$
$$\frac{\frac{\partial^2 f}{\partial \mathbf{y}^2}}{\frac{\partial^2 f}{\partial \mathbf{y}^2}} = (f_{-1,-1} - f_{-1,1} - f_{1,-1} + f_{1,1})/4$$

• Orientation = blurred gradient

$$\mathbf{u}_l(x, y) = \nabla_{\sigma_o} P_l(x, y)$$
$$\sigma_o = 4.5$$

$$[\cos\theta,\sin\theta] = \mathbf{u}/|\mathbf{u}|$$

# **Descriptor Vector**

- Rotation Invariant Frame
  - Scale-space position (x, y, s) + orientation ( $\theta$ )

# **MSOP** descriptor vector

- 8x8 oriented patch sampled at 5 x scale. See TR for details.
- Sampled from  $P_l(x,y) \ast g_{2 \times \sigma_p}(x,y)$  with spacing=5

# **MSOP** descriptor vector

- 8x8 oriented patch sampled at 5 x scale. See TR for details.
- Bias/gain normalisation:  $I' = (I \mu)/\sigma$
- Wavelet transform

# Detections at multiple scales

Figure 1. Multi-scale Oriented Patches (MOPS) extracted at five pyramid levels from one of the Matier images. The boxes show the feature orientation and the region from which the descriptor vector is sampled.

#### Summary

- Multi-scale Harris corner detector
- Sub-pixel refinement
- Orientation assignment by gradients
- Blurred intensity patch as descriptor

# Feature matching

- Exhaustive search
  - for each feature in one image, look at *all* the other features in the other image(s)
- Hashing
  - compute a short descriptor from each feature vector, or hash longer descriptors (randomly)
- Nearest neighbor techniques
  - *k*-trees and their variants (Best Bin First)

# Wavelet-based hashing

 Compute a short (3-vector) descriptor from an 8x8 patch using a Haar "wavelet"

- Quantize each value into 10 (overlapping) bins (10<sup>3</sup> total entries)
- [Brown, Szeliski, Winder, CVPR'2005]

# Nearest neighbor techniques

- *k*-D tree and
- Best Bin First (BBF)

Figure 6: kd-tree with 8 data points labelled A-H, dimension of space k=2. On the right is the full tree, the leaf nodes containing the data points. Internal node information consists of the dimension of the cut plane and the value of the cut in that dimension. On the left is the 2D feature space carved into various sizes and shapes of bin, according to the distribution of the data points. The two representations are isomorphic. The situation shown on the left is after initial tree traversal to locate the bin for query point "+" (contains point D). In standard search, the closest nodes in the tree are examined first (starting at C). In BBF search, the closest bins to query point q are examined first (starting at B). The latter is more likely to maximize the overlap of (i) the hypersphere centered on q with radius  $D_{cur}$ , and (ii) the hyperrectangle of the bin to be searched. In this case, BBF search reduces the number of leaves to examine, since once point B is discovered, all other branches can be pruned.
