

## Smart Plot: **fplot**

- Use **fplot** to make a line plot over a specific range with **adaptive** steps.
- You may assign a function in a string form to **fplot**.<sup>1</sup>

```
1 clear; clc; close all;  
2  
3 fplot("sin(1 / x)", [-0.05, 0.05]); grid on;
```

---

<sup>1</sup>Warning: **fplot** will not accept character vector or string inputs in a future release.

## errorbar<sup>2</sup>

```
1 clear; clc; close all;
2
3 x = 0 : 10 : 100;
4 y = [20 30 45 40 60 65 80 75 95 90];
5 yneg = [1 3 5 3 5 3 6 4 3 3];
6 ypos = [2 5 3 5 2 5 2 2 5 5];
7 xneg = [1 3 5 3 5 3 6 4 3 3];
8 xpos = [2 5 3 5 2 5 2 2 5 5];
9 errorbar(x, y, yneg, ypos, xneg, xpos, "o");
10 grid on;
```

---

<sup>2</sup>See <https://www.mathworks.com/help/matlab/ref/errorbar.html>.

## Pie Chart

```
1 clear; clc; close all;
2
3 X = rand(1, 5);
4 labels = {"A", "B", "C", "D", "E"};
5 explode = [0, 1, 0, 1, 0];
6 pie(X, explode, labels);
```

- Use **pie** to create a pie chart.<sup>3</sup>
- Note that the explode vector is used to offset slices for the nonzero elements.

---

<sup>3</sup>See <https://www.mathworks.com/help/matlab/ref/pie.html>.

## market\_values

```
1 clear; clc; close all;
2
3 [~, ~, raw] = xlsread("twse_mktValue.xlsx");
4
5 stock_ticks = string(raw(4 : end, 1));
6 idx = strcmp(raw(:, 3), "-"); % Find all "-"s.
7 raw(idx, 3) = {0};           % Replace them by 0.
8 market_values = [raw{4 : end, 3}]';
9
10 tbl = table(stock_ticks, market_values);
11 figure;
12 wordcloud(tbl, "stock_ticks", "market_values");
```

- Use **strcmp** to compare strings and return a boolean vector.
- Use **wordcloud** to create a word cloud chart from text data.<sup>4</sup>

---

<sup>4</sup>See <https://www.mathworks.com/help/matlab/ref/wordcloud.html>.

## Contours<sup>5</sup>

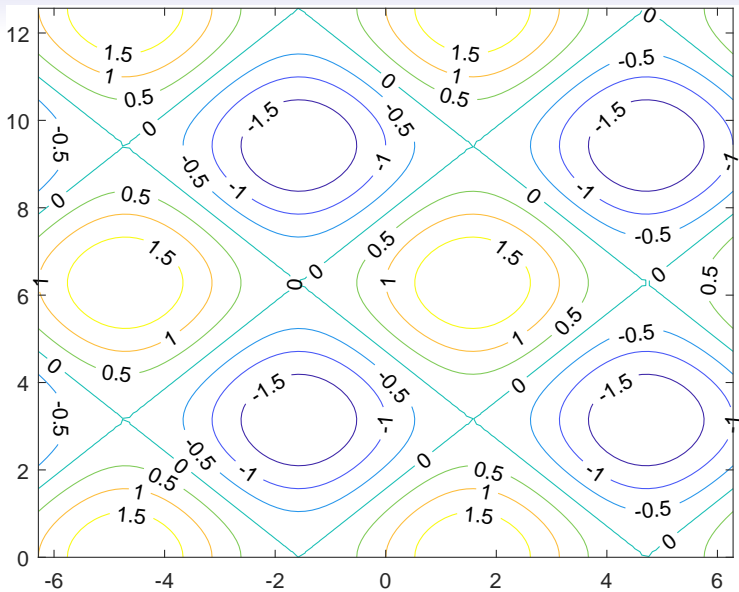

- Use **meshgrid** to partition the specified range of  $x$  and  $y$ .
- Note that the return values are in form of matrices. (Why?)

```
1 clear; clc; close all;
2
3 x = linspace(-2 * pi, 2 * pi);
4 y = linspace(0, 4 * pi);
5 [X, Y] = meshgrid(x, y);
6 Z = sin(X) + cos(Y); % Using vectorization.
7 figure; contour(X, Y, Z, "showtext", "on");
```

---

<sup>5</sup>See <https://www.mathworks.com/help/matlab/ref/contour.html>.

You may try **contourf**.

## Quiver (Velocity) Plot

- Use **quiver**( $x, y, u, v$ ) to plot a vector ( $u, v$ ) at the coordinate ( $x, y$ ).
- Use **peaks** with a positive number as sample size to generate a set of 3d points.<sup>6</sup>

```
1 clear; clc; close all;
2
3 [x, y, z] = peaks(20);
4 [u, v] = gradient(z);
5 figure; hold on; grid on;
6 contour(x, y, z, 10);
7 quiver(x, y, u, v);
```

---

<sup>6</sup>See <https://www.mathworks.com/help/matlab/ref/peaks.html>

# Mesh Plot

- Use **mesh** to draw a wireframe mesh.

```
1 clear; clc; close all;
2
3 x = linspace(-3, 3, 50);
4 y = x + pi / 2;
5 [X, Y] = meshgrid(x, y);
6 Z = cos(X) .* sin(Y);
7 figure; mesh(X, Y, Z); grid on;
8 xlabel("x"); ylabel("y"); zlabel("z");
```

# Surface Plot

- Use **surf** to draw a colored surface.
- Try **meshz**, **meshc**, **surfc**, and **waterfall**.

```
1 clear; clc; close all;
2
3 x = linspace(-2, 2, 25);
4 y = linspace(-2, 2, 25);
5 [X, Y] = meshgrid(x, y); % form all x-y pairs
6 Z = X .* exp(-X.^2 - Y.^2);
7 surf(X, Y, Z);
8 xlabel("x"); ylabel("y"); zlabel("z");
```

## Exercise

- Write a program to draw a surface plot for  $\text{sinc}(R) = \frac{\sin(R)}{R}$ .
- Note that there exists a singularity at  $R = 0$ , which should be removed by replacing a zero with  $\text{eps} = 2.2204 \times 10^{-16}$ .

```
1 clear; clc; close all;
2
3 [X, Y] = meshgrid(linspace(-10, 10, 51));
4 R = sqrt(X.^ 2 + Y.^ 2);
5 R(R == 0) = eps; % Avoid the singularity.
6 Z = sin(R) ./ R;
7 surf(X, Y, Z);
```

## 3D Line Plot

- Use **plot3** to draw a 3d curve.

```
1 clear; clc; close all;
2
3 t = linspace(0, 10 * pi, 100);
4 x = t .* sin(t); y = t .* cos(t);
5
6 figure;
7 plot3(x, y, t); hold on;
8 plot3(x, y, -t, "r");
9 axis equal; grid on;
```

## Misc<sup>9</sup>

- Use the button *Rotate 3D* to change the view angle.
- Use **view** to set the view angle.<sup>7</sup>
- Try **colorbar** and **colormap**.<sup>8</sup>

```
1 clear; clc; close all;
2
3 peaks;
4 view([117, 58]); % View angle in degree.
5 colorbar; % Appends a colorbar to the current axes.
6 colormap summer; % Change the colormap.
```

---

<sup>7</sup>az: azimuth (horizontal) rotation; el: vertical elevation.

<sup>8</sup>See <https://www.mathworks.com/help/matlab/ref/colormap.html>.

<sup>9</sup>See

## Peaks

```
1 >> Lecture 4
2 >>
3 >>          -- Functions
4 >>
```

# Motivation

- A large and complicated problem would be conquered by solving its subproblems.
- So the first step is **problem decomposition**, that is, separating tasks into smaller self-contained units.
- This is also beneficial to **code reuse** without copying the codes.
- Note that **bugs propagate across the program when you copy and paste the codes.**

# Function

- A **function** is a piece of program code that accepts **input arguments** from the caller, and then returns **output arguments** to the caller.
- In MATLAB, the syntax of functions is similar to math functions,

$$y = f(x),$$

where  $x$  is the input and  $y$  is the output.

# User-Defined Functions

- We can define a new function as follows:

```
1 function [outputVar] = function_name(inputVar)
2     % What to do.
3 end
```

- This function should be saved in a file with the function name!
- Note that the input/output variables can be optional.

## Example: Addition of Two Numbers

```
1 function z = myAdd(x, y)
2     % Input: x, y (any two numbers).
3     % Output: z (sum of x and y).
4     z = x + y;
5 end
```

- It seems bloody trivial.
- The truth is that the plus operator is actually the function **plus**.<sup>10</sup>
- Also true for all the operators like  $+$ .

---

<sup>10</sup>See <https://www.mathworks.com/help/matlab/ref/plus.html>.

## Variable-length Input Argument List<sup>11</sup> (Optional)

- We can know the number of input arguments for the function executed by **nargin**.
- **varargin** is an input variable in a function definition statement that enables the function to accept any number of input arguments.
  - It must be declared as the last input argument and collects all the inputs from that point onwards.
- The variable **varargout** is a special word similar to **varargin** but for outputs.

---

<sup>11</sup>See <https://www.mathworks.com/help/matlab/ref/varargin.html>. 

## Example

```
1 function ret = myAdd(varargin)
2
3     switch nargin
4         case 0
5             disp("No input.");
6         case 1
7             ret = varargin{1};
8         case {2, 3}
9             ret = sum([varargin{:}]);
10        otherwise
11            error("Too many inputs.");
12    end
13
14 end
```

# Variable Scope

- Variables in a function are known as **local variables**, existing only for the function.
- These variables are wiped out when the function finishes its task.
- You may trace the data flow in the program by using the **debugger**.<sup>12</sup>
  - Let's set some **breakpoints**!!!

---

<sup>12</sup>See [https://www.mathworks.com/help/matlab/matlab\\_prog/debugging-process-and-features.html](https://www.mathworks.com/help/matlab/matlab_prog/debugging-process-and-features.html).

# Example

```
1 clear; clc;
2
3 x = 0;
4 for i = 1 : 5
5     addOne(x);
6     disp(x); % output ?
7 end
```

```
1 function addOne(x)
2     x = x + 1;
3 end
```

# Function Handles & Anonymous Functions

- Anonymous functions are used once and not written in the standard form of functions, for example,

```
1 f = @(x) x.^2 + 1 % f is a function handle.
```

- However, they contain **only single statement**.
- Besides, we use **function handles**<sup>13</sup> to handle functions.
- This is also called **lambda expressions**.
- You can also assign an existing function to a handle, for example,

```
1 g = @sin
```

---

<sup>13</sup>You may refer to [https://en.wikipedia.org/wiki/Function\\_pointer](https://en.wikipedia.org/wiki/Function_pointer).  
The truth is that every function name is an alias of the function address!

## More Examples<sup>14,15,16</sup>

```
1 function y = parabolicFunGen(a, b, c)
2     y = @(x) a * x .^ 2 + b * x + c;
3 end
```

```
1 function y = getSlope(f, x0)
2     eps = 1e-9;
3     y = (f(x0 + eps) - f(x0)) / eps;
4 end
```

```
1 function y = differentiate(f)
2     eps = 1e-9;
3     y = @(x) (f(x + eps) - f(x)) / eps;
4 end
```

<sup>14</sup>Thanks to a lively class discussion (MATLAB244) on August 22, 2014.

<sup>15</sup>Contribution by Ms. Queenie Chang (MAT25108) on March 18, 2015.

<sup>16</sup>Thanks to a lively class discussion (MATLAB260) on September 16, 2015.

## Vectorization (Revisited)

- We can apply a function to each element of array by **arrayfun**.<sup>17</sup>

```
1 B = arrayfun(@(x) 2 * x, A) % Equivalent to 2 * A.
```

- **cellfun** is similar to **arrayfun** but applied to cells.<sup>18</sup>

```
1 >> data = {"NTU", "CSIE", [], "MATLAB"};  
2 >> isempty(data) % Output 0.  
3 >> cellfun(@isempty, data) % Output 0 0 1 0.
```

---

<sup>17</sup>See <https://www.mathworks.com/help/matlab/ref/arrayfun.html>.

<sup>18</sup>See <https://www.mathworks.com/help/matlab/ref/cellfun.html>.

## Error and Error Handling

- You can issue/throw an **error** if you **do not allow** the callee for some situations.

```
1 if bad_condition
2     error("So wrong."); % Interrupt the normal flow.
3 end
```

- As an app programmer, you should use a **try-catch** statement to handle errors.

```
1 try
2     % Normal operations.
3 catch
4     % Handler operations.
5 end
```

## Example: Combinations

- For all nonnegative integers  $n \geq k$ ,  $\binom{n}{k}$  is given by

$$\binom{n}{k} = \frac{n!}{k!(n-k)!}.$$

- Note that **factorial**( $n$ ) returns  $n!$ .

```
1 clear; clc;
2
3 n = input("n = ? ");
4 k = input("k = ? ");
5 y = factorial(n) / (factorial(k) * factorial(n - k))
6 disp('End of program.');
```

- Try  $n = 2, k = 5$ .
- However, **factorial**(-3) is not allowed!
- The program is not designed to handle this error, so it is interrupted in Line 5 and does not reach the end of program.
- Add error handling to the program:

```
1 clear; clc;
2
3 n = input("n = ? ");
4 k = input("k = ? ");
5 try
6     y = factorial(n) / (factorial(k) * ...
7         factorial(n - k))
8 catch e % capture the thrown exception
9     disp("Error: " + e.message); % show the message
10 end
11 disp("End of program.");
```

```

3 >>      -- Special Topic: Text Processing
4 >>
```

## (Most) Common Codec: ASCII<sup>20</sup>

- Everything in the computer is encoded in binary.
- ASCII is a character-encoding scheme originally based on the English alphabet that encodes 128 specified characters into the 7-bit binary integers (see the next page).
- Unicode<sup>19</sup> became a standard for the modern systems from 2007.
  - Unicode is backward compatible with ASCII because ASCII is a subset of Unicode.

---

<sup>19</sup>See [Unicode 8.0 Character Code Charts](#).

<sup>20</sup>Codec: coder-decoder; ASCII: American Standard Code for Information Interchange, also see <http://zh.wikipedia.org/wiki/ASCII>.

## Characters and Strings (Revisited)

- Before R2017a, a text is a sequence of characters, just like numeric arrays.
  - For example, 'ntu'.
- Most built-in functions can be applied to string arrays.

```
1 clear; clc;
2
3 s1 = 'ntu'; s2 = 'csie';
4 s = {s1, s2};
5 upper(s) % output: {'NTU', 'CSIE'}
```

- Since R2017a, you can create a string by enclosing a piece of text in **double quotes**.<sup>21</sup>
  - For example, "ntu".
- You can find a big difference between characters and strings in this example:

```
1 clear; clc;
2
3 s1 = 'ntu'; s2 = 'NTU';
4 s1 + s2 % output: 188 200 202
5
6 s3 = string(s1); s4 = string(s2);
7 s3 + s4 % output: "ntuNTU"
```

---

<sup>21</sup>See <https://www.mathworks.com/help/matlab/ref/string.html>.

## Selected Text Operations<sup>22</sup>

<b>sprintf</b>	Format data into string.
<b>strcat</b>	Concatenate strings horizontally.
<b>contains</b>	Determine if pattern is in string.
<b>count</b>	Count occurrences of pattern in string.
<b>endsWith</b>	Determine if string ends with pattern.
<b>startsWith</b>	Determine if string starts with pattern.
<b>strfind</b>	Find one string within another.
<b>replace</b>	Find and replace substrings in string array.
<b>split</b>	Split strings in string array.
<b>strjoin</b>	Join text in array.
<b>lower</b>	Convert string to lowercase.
<b>upper</b>	Convert string to uppercase.
<b>reverse</b>	Reverse order of characters in string.

---

<sup>22</sup>See [https:](https://www.mathworks.com/help/matlab/characters-and-strings.html)

[//www.mathworks.com/help/matlab/characters-and-strings.html](https://www.mathworks.com/help/matlab/characters-and-strings.html)

# Introduction to Regular Expressions<sup>23</sup>

- A regular expression, also called a pattern, is an expression used to specify a set of strings required for a particular purpose.
  - Check this: <https://regexone.com>.

---

<sup>23</sup>See [https://en.wikipedia.org/wiki/Regular\\_expression](https://en.wikipedia.org/wiki/Regular_expression); also [https://www.mathworks.com/help/matlab/matlab\\_prog/regular-expressions.html](https://www.mathworks.com/help/matlab/matlab_prog/regular-expressions.html).

## Example

```
1 >> text = 'bat cat can car coat court CUT ct ...  
    CAT-scan';  
2 >> pattern = 'c[aeiou]+t';  
3 >> start_idx = regexp(text, pattern)  
4  
5 start_idx =  
6  
7          5      17
```

- The pattern 'c[aeiou]+t' indicates a set of strings:
  - c must be the first character;
  - c must be followed by one of the characters in the brackets [aeiou], followed by t as the last character;
  - in particular, [aeiou] must occur one or more times, as indicated by the + operator.

## Metacharacters<sup>24</sup>

Operator	Definition
	Boolean OR.
*	0 or more times consecutively.
?	0 times or 1 time.
+	1 or more times consecutively.
{n}	exactly n times consecutively.
{m, }	at least m times consecutively.
{, n}	at most n times consecutively.
{m, n}	at least m times, but no more than n times consecutively.

---

<sup>24</sup>See <https://www.mathworks.com/help/matlab/ref/regexp.html>.

Operator	Definition
.	any single character, including white space.
$[c_1c_2c_3]$	any character contained within the brackets.
$[\wedge c_1c_2c_3]$	any character not contained within the brackets.
$[c_1-c_2]$	any character in the range of $c_1$ through $c_2$ .
$\backslash s$	any white-space character.
$\backslash w$	a word; any alphabetic, numeric, or underscore character.
$\backslash W$	not a word.
$\backslash d$	any numeric digit; equivalent to $[0-9]$ .
$\backslash D$	no numeric digit; equivalent to $[\wedge 0-9]$ .

## Output Keywords

Keyword	Output
'start'	starting indices of all matches, by default
'end'	ending indices of all matches
'match'	text of each substring that matches the pattern
'tokens'	text of each captured token
'split'	text of nonmatching substrings
'names'	name and text of each named token

# Examples

```
1 clear; clc;
2
3 text1 = {'Madrid, Spain', 'Romeo and Juliet', ...
          'MATLAB is great'};
4 tokens = regexp(text1, '\s', 'split')
5
6 text2 = 'EXTRA! The regexp function helps you ...
          relax.';
7 matches = regexp(text2, '\w*x\w*', 'match')
```

## Exercise: Listing Filtered Files

```
1 clear; clc;
2
3 file_list = dir;
4 filenames = {file_list(:).name};
5 A = regexp(filenames, '.*\.m', 'match');
6 mask = cellfun(@(x) ~isempty(x), A);
7 cellfun(@(f) fprintf('%s\\%s\n', pwd, f{:})), A(mask))
```

## Example: By Names

- You can associate names with tokens so that they are more easily identifiable.
- For example,

```
1 >> str = 'Here is a date: 01-Apr-2020';
2 >> expr = '(?<day>\d+)-(?<month>\w+)-(?<year>\d+)';
3 >> mydate = regexp(str, expr, 'names')
4
5 mydate =
6
7         day: '01'
8         month: 'Apr'
9         year: '2020'
```

## Exercise: Web Crawler

- Write a script which collects the names of html tags by defining a token within a regular expression.
- For example,

```
1 >> str = '<title>My Title</title><p>Here is some ...  
    text.</p>';  
2 >> pattern = '<(\w+).*>.*</\1>';  
3 >> [tokens, matches] = regexp(str, pattern, ...  
    'tokens', 'match')
```

# More Regexp Functions

- See **regexpi**, **regexprep**, and **regexptranslate**.

```

## Spreadsheets: Excel/CSV Files (Revisited)

- The command **xlsread**(*filename*) reads excel files, for example,

```
1 [~, ~, raw] = xlsread("2330.xlsx");
```

- By default, it returns a numeric matrix.
- The text part is the 2nd output, separated from the numeric part.
- You may consider the whole spreadsheet by using the 3rd output (stored in a cell array).
- Note that you can use ~ to drop the output value.

## More Tips for Excel Files

- You can specify the range.
  - For example, the string argument "B:B" is used to import column B.
  - If you need a single value, say the cell B1, just use "B1:B1".<sup>25</sup>
- You could specify the worksheet by the sheet name<sup>26</sup> or the sheet number.
- You could refer to the document for more details.<sup>27</sup>

---

<sup>25</sup>Contribution by Mr. Tsung-Yu Hsieh (MAT24409) on August 27, 2014.

<sup>26</sup>The default sheet name is “工作表”.

<sup>27</sup>See <https://www.mathworks.com/help/matlab/ref/xlsread.html>.

## Mat Files<sup>28</sup>

- Recall that I/O is costly.
- To save time, you may consider **save** matrices to the disk; for example,

```
1 data1 = rand(1, 10);  
2 data2 = ones(10);  
3 save('trial.mat', 'data1', 'data2');
```

- You can use **load** to fetch the data from mat files.

```
1 load('trial.mat');
```

---

<sup>28</sup>See <https://www.mathworks.com/help/matlab/ref/save.html>.

## Selected Read/Write Functions

- For text data, see <https://www.mathworks.com/help/matlab/text-files.html>.
  - Try **dlmread**, **dlmwrite**, **csvread**, **csvwrite**, **textread**/**textscan**.
- For images, see [https://www.mathworks.com/help/matlab/images\\_images.html](https://www.mathworks.com/help/matlab/images_images.html).
- For video and audio, see <https://www.mathworks.com/help/matlab/audio-and-video.html>.

## Selected File Operations<sup>29</sup>

<b>cd</b>	Change current folder.
<b>pwd</b>	Identify current folder.
<b>ls</b>	List folder contents by chars.
<b>dir</b>	List folder contents by structures.
<b>exist</b>	Check existence of variable, script, function, folder, or class.
<b>mkdir</b>	Make new folder.
<b>visdiff</b>	Compare two files or folders.

---

<sup>29</sup>See

## Example: Pooling Data from Multiple Files<sup>30</sup>

```
1 clear; clc;
2
3 cd('./stocks'); % enter the folder
4 files = dir; % get all files in the current folder
5 files = files(3 : end); % drop the first two
6 names = {files(:).name}; % get all file names
7 filter = endsWith(names, '.xlsx'); % filter by .xlsx
8 names = names(filter);
9
10 pool = cell(length(names), 2);
11 for i = 1 : length(names)
12     [~, ~, raw] = xlsread(names{i});
13     pool(i, :) = {names{i}(1 : 4), raw};
14 end
15 save('data_pool', 'pool');
```
