Spread of Nonbenchmark Bonds

- Model prices calculated by the calibrated tree as a rule do not match market prices of nonbenchmark bonds.
- The incremental return over the benchmark bonds is called spread.
- If we add the spread uniformly over the short rates in the tree, the model price will equal the market price.
- We will apply the spread concept to option-free bonds here.

- We illustrate the idea with an example.
- Start with the tree on p. 799.
- Consider a security with cash flow C_i at time *i* for i = 1, 2, 3.
- Its model price is p(s), which is equal to

$$\begin{aligned} \frac{1}{1.04+s} \times \left[\, C_1 + \frac{1}{2} \times \frac{1}{1.03526+s} \times \left(C_2 + \frac{1}{2} \left(\frac{C_3}{1.02895+s} + \frac{C_3}{1.04343+s} \right) \right) + \right. \\ \left. \frac{1}{2} \times \frac{1}{1.05289+s} \times \left(C_2 + \frac{1}{2} \left(\frac{C_3}{1.04343+s} + \frac{C_3}{1.06514+s} \right) \right) \right]. \end{aligned}$$

• Given a market price of P, the spread is the s that solves P = p(s).

- The model price p(s) is a monotonically decreasing, convex function of s.
- We will employ the Newton-Raphson root-finding method to solve p(s) - P = 0 for s.
- But a quick look at the equation above reveals that evaluating p'(s) directly is infeasible.
- Fortunately, the tree can be used to evaluate both p(s)and p'(s) during backward induction.

- Consider an arbitrary node A in the tree associated with the short rate r.
- In the process of computing the model price p(s), a price $p_A(s)$ is computed at A.
- Prices computed at A's two successor nodes B and C are discounted by r + s to obtain $p_A(s)$ as follows,

$$p_{\rm A}(s) = c + \frac{p_{\rm B}(s) + p_{\rm C}(s)}{2(1+r+s)},$$

where c denotes the cash flow at A.

• To compute $p'_{A}(s)$ as well, node A calculates

$$p'_{\rm A}(s) = \frac{p'_{\rm B}(s) + p'_{\rm C}(s)}{2(1+r+s)} - \frac{p_{\rm B}(s) + p_{\rm C}(s)}{2(1+r+s)^2}.$$
 (83)

- This is easy if $p'_{\rm B}(s)$ and $p'_{\rm C}(s)$ are also computed at nodes B and C.
- Apply the above procedure inductively to yield p(s) and p'(s) at the root (p. 803).
- This is called the differential tree method.^a

^aLyuu (1999).

- Let C represent the number of times the tree is traversed, which takes $O(n^2)$ time.
- The total running time is $O(Cn^2)$.
- In practice \mathcal{C} is a small constant.
- The memory requirement is O(n).

Number of	Running	Number of	Number of	Running	Number of

75MHz Sun SPARCstation 20.

- Consider a three-year, 5% bond with a market price of 100.569.
- Assume the bond pays annual interest.
- The spread can be shown to be 50 basis points over the tree (p. 807).
- Note that the idea of spread does not assume parallel shifts in the term structure.
- It also differs from the yield spread (p. 111) and static spread (p. 112) of the nonbenchmark bond over an otherwise identical benchmark bond.

Fixed-Income Options

- Consider a two-year 99 European call on the three-year, 5% Treasury.
- Assume the Treasury pays annual interest.
- From p. 811 the three-year Treasury's price minus the \$5 interest could be \$102.046, \$100.630, or \$98.579 two years from now.
- Since these prices do not include the accrued interest, we should compare the strike price against them.
- The call is therefore in the money in the first two scenarios, with values of \$3.046 and \$1.630, and out of the money in the third scenario.

Fixed-Income Options (continued)

- The option value is calculated to be \$1.458 on p. 811(a).
- European interest rate puts can be valued similarly.
- Consider a two-year 99 European put on the same security.
- At expiration, the put is in the money only if the Treasury is worth \$98.579 without the accrued interest.
- The option value is computed to be \$0.096 on p. 811(b).

Fixed-Income Options (concluded)

- The present value of the strike price is $PV(X) = 99 \times 0.92101 = 91.18.$
- The Treasury is worth B = 101.955 (the PV of 105).
- The present value of the interest payments during the life of the options is

$$PV(I) = 5 \times 0.96154 + 5 \times 0.92101 = 9.41275.$$

- The call and the put are worth C = 1.458 and P = 0.096, respectively.
- Hence the put-call parity is preserved:

$$C = P + B - PV(I) - PV(X).$$

Delta or Hedge Ratio

- How much does the option price change in response to changes in the price of the underlying bond?
- This relation is called delta (or hedge ratio) defined as

$$\frac{O_{\rm h} - O_{\ell}}{P_{\rm h} - P_{\ell}}.$$

- In the above $P_{\rm h}$ and P_{ℓ} denote the bond prices if the short rate moves up and down, respectively.
- Similarly, $O_{\rm h}$ and O_{ℓ} denote the option values if the short rate moves up and down, respectively.

Delta or Hedge Ratio (concluded)

- Since delta measures the sensitivity of the option value to changes in the underlying bond price, it shows how to hedge one with the other.
- Take the call and put on p. 811 as examples.
- Their deltas are

$$\frac{0.774 - 2.258}{99.350 - 102.716} = 0.441,$$

$$\frac{0.200 - 0.000}{99.350 - 102.716} = -0.059,$$

respectively.

Volatility Term Structures

- The binomial interest rate tree can be used to calculate the yield volatility of zero-coupon bonds.
- Consider an *n*-period zero-coupon bond.
- First find its yield to maturity $y_{\rm h}$ (y_{ℓ} , respectively) at the end of the initial period if the rate rises (declines, respectively).
- The yield volatility for our model is defined as $(1/2) \ln(y_h/y_\ell).$

- For example, based on the tree on p. 793, the two-year zero's yield at the end of the first period is 5.289% if the rate rises and 3.526% if the rate declines.
- Its yield volatility is therefore

$$\frac{1}{2} \ln\left(\frac{0.05289}{0.03526}\right) = 20.273\%.$$

- Consider the three-year zero-coupon bond.
- If the rate rises, the price of the zero one year from now will be

$$\frac{1}{2} \times \frac{1}{1.05289} \times \left(\frac{1}{1.04343} + \frac{1}{1.06514}\right) = 0.90096.$$

• Thus its yield is
$$\sqrt{\frac{1}{0.90096}} - 1 = 0.053531.$$

• If the rate declines, the price of the zero one year from now will be

$$\frac{1}{2} \times \frac{1}{1.03526} \times \left(\frac{1}{1.02895} + \frac{1}{1.04343}\right) = 0.93225.$$

- Thus its yield is $\sqrt{\frac{1}{0.93225}} 1 = 0.0357.$
- The yield volatility is hence

$$\frac{1}{2} \ln\left(\frac{0.053531}{0.0357}\right) = 20.256\%,$$

slightly less than the one-year yield volatility.

- This is consistent with the reality that longer-term bonds typically have lower yield volatilities than shorter-term bonds.
- The procedure can be repeated for longer-term zeros to obtain their yield volatilities.

- We started with v_i and then derived the volatility term structure.
- In practice, the steps are reversed.
- The volatility term structure is supplied by the user along with the term structure.
- The v_i —hence the short rate volatilities via Eq. (79) on p. 773—and the r_i are then simultaneously determined.
- The result is the Black-Derman-Toy model.^a

^aBlack, Derman, and Toy (1990).

- Suppose the user supplies the volatility term structure which results in $(v_1, v_2, v_3, ...)$ for the tree.
- The volatility term structure one period from now will be determined by $(v_2, v_3, v_4, ...)$ not $(v_1, v_2, v_3, ...)$.
- The volatility term structure supplied by the user is hence not maintained through time.
- This issue will be addressed by other types of (complex) models.

Foundations of Term Structure Modeling

[Meriwether] scoring especially high marks in mathematics — an indispensable subject for a bond trader. — Roger Lowenstein, When Genius Failed (2000) [The] fixed-income traders I knew seemed smarter than the equity trader $[\cdots]$ there's no competitive edge to being smart in the equities business[.] — Emanuel Derman, My Life as a Quant (2004)

Terminology

- A period denotes a unit of elapsed time.
 - Viewed at time t, the next time instant refers to time t + dt in the continuous-time model and time t + 1 in the discrete-time case.
- Bonds will be assumed to have a par value of one unless stated otherwise.
- The time unit for continuous-time models will usually be measured by the year.

Standard Notations

The following notation will be used throughout.

- t: a point in time.
- r(t): the one-period riskless rate prevailing at time t for repayment one period later

(the instantaneous spot rate, or short rate, at time t).

P(t,T): the present value at time t of one dollar at time T.

Standard Notations (continued)

- r(t,T): the (T-t)-period interest rate prevailing at time t stated on a per-period basis and compounded once per period—in other words, the (T-t)-period spot rate at time t.
- F(t,T,M): the forward price at time t of a forward contract that delivers at time T a zero-coupon bond maturing at time $M \ge T$.

Standard Notations (concluded)

- f(t, T, L): the L-period forward rate at time T implied at time t stated on a per-period basis and compounded once per period.
- f(t,T): the one-period or instantaneous forward rate at time T as seen at time t stated on a per period basis and compounded once per period.
 - It is f(t, T, 1) in the discrete-time model and f(t, T, dt) in the continuous-time model.
 - Note that f(t,t) equals the short rate r(t).

Fundamental Relations

• The price of a zero-coupon bond equals

$$P(t,T) = \begin{cases} (1+r(t,T))^{-(T-t)}, & \text{in discrete time,} \\ e^{-r(t,T)(T-t)}, & \text{in continuous time.} \end{cases}$$

- r(t,T) as a function of T defines the spot rate curve at time t.
- By definition,

$$f(t,t) = \begin{cases} r(t,t+1), & \text{in discrete time,} \\ r(t,t), & \text{in continuous time.} \end{cases}$$

Fundamental Relations (continued)

• Forward prices and zero-coupon bond prices are related:

$$F(t, T, M) = \frac{P(t, M)}{P(t, T)}, \quad T \le M.$$
 (84)

- The forward price equals the future value at time T of the underlying asset (see text for proof).
- Equation (84) holds whether the model is discrete-time or continuous-time.

Fundamental Relations (continued)

• Forward rates and forward prices are related definitionally by

$$f(t,T,L) = \left(\frac{1}{F(t,T,T+L)}\right)^{1/L} - 1 = \left(\frac{P(t,T)}{P(t,T+L)}\right)^{1/L} - 1$$
(85)

in discrete time.

– The analog to Eq. (85) under simple compounding is

$$f(t, T, L) = \frac{1}{L} \left(\frac{P(t, T)}{P(t, T + L)} - 1 \right).$$
Fundamental Relations (continued)

• In continuous time,

$$f(t,T,L) = -\frac{\ln F(t,T,T+L)}{L} = \frac{\ln(P(t,T)/P(t,T+L))}{L}$$
(86)

by Eq. (84) on p. 831.

• Furthermore,

$$f(t,T,\Delta t) = \frac{\ln(P(t,T)/P(t,T+\Delta t))}{\Delta t} \to -\frac{\partial \ln P(t,T)}{\partial T}$$
$$= -\frac{\partial P(t,T)/\partial T}{P(t,T)}.$$

Fundamental Relations (continued)

• So

$$f(t,T) \equiv \lim_{\Delta t \to 0} f(t,T,\Delta t) = -\frac{\partial P(t,T)/\partial T}{P(t,T)}, \quad t \le T.$$
(87)

• Because Eq. (87) is equivalent to

$$P(t,T) = e^{-\int_{t}^{T} f(t,s) \, ds},$$
(88)

the spot rate curve is

$$r(t,T) = \frac{1}{T-t} \int_t^T f(t,s) \, ds.$$

Fundamental Relations (concluded)

• The discrete analog to Eq. (88) is

$$P(t,T) = \frac{1}{(1+r(t))(1+f(t,t+1))\cdots(1+f(t,T-1))}$$

• The short rate and the market discount function are related by

$$r(t) = -\left. \frac{\partial P(t,T)}{\partial T} \right|_{T=t}$$

Risk-Neutral Pricing

- Assume the local expectations theory.
- The expected rate of return of any riskless bond over a single period equals the prevailing one-period spot rate.

- For all t + 1 < T,

$$\frac{E_t[P(t+1,T)]}{P(t,T)} = 1 + r(t).$$
(89)

Relation (89) in fact follows from the risk-neutral valuation principle.^a

^aTheorem 14 on p. 447.

Risk-Neutral Pricing (continued)

- The local expectations theory is thus a consequence of the existence of a risk-neutral probability π .
- Rewrite Eq. (89) as

$$\frac{E_t^{\pi}[P(t+1,T)]}{1+r(t)} = P(t,T).$$

 It says the current spot rate curve equals the expected spot rate curve one period from now discounted by the short rate.

Risk-Neutral Pricing (continued)

• Apply the above equality iteratively to obtain

$$P(t,T) = E_t^{\pi} \left[\frac{P(t+1,T)}{1+r(t)} \right]$$

= $E_t^{\pi} \left[\frac{E_{t+1}^{\pi} [P(t+2,T)]}{(1+r(t))(1+r(t+1))} \right] = \cdots$
= $E_t^{\pi} \left[\frac{1}{(1+r(t))(1+r(t+1))\cdots(1+r(T-1))} \right].$ (90)

Risk-Neutral Pricing (concluded)

- Equation (89) on p. 836 can also be expressed as $E_t[P(t+1,T)] = F(t,t+1,T).$
 - Verify that with, e.g., Eq. (84) on p. 831.
- Hence the forward price for the next period is an unbiased estimator of the expected bond price.

Continuous-Time Risk-Neutral Pricing

- In continuous time, the local expectations theory implies $P(t,T) = E_t \left[e^{-\int_t^T r(s) \, ds} \right], \quad t < T. \quad (91)$
- Note that $e^{\int_t^T r(s) ds}$ is the bank account process, which denotes the rolled-over money market account.
- When the local expectations theory holds, riskless arbitrage opportunities are impossible.

Interest Rate Swaps

- Consider an interest rate swap made at time t with payments to be exchanged at times t_1, t_2, \ldots, t_n .
- The fixed rate is c per annum.
- The floating-rate payments are based on the future annual rates $f_0, f_1, \ldots, f_{n-1}$ at times $t_0, t_1, \ldots, t_{n-1}$.
- For simplicity, assume $t_{i+1} t_i$ is a fixed constant Δt for all i, and the notional principal is one dollar.
- If $t < t_0$, we have a forward interest rate swap.
- The ordinary swap corresponds to $t = t_0$.

Interest Rate Swaps (continued)

- The amount to be paid out at time t_{i+1} is $(f_i c) \Delta t$ for the floating-rate payer.
- Simple rates are adopted here.
- Hence f_i satisfies

$$P(t_i, t_{i+1}) = \frac{1}{1 + f_i \Delta t}.$$

Interest Rate Swaps (continued)

• The value of the swap at time t is thus

$$\sum_{i=1}^{n} E_{t}^{\pi} \left[e^{-\int_{t}^{t_{i}} r(s) \, ds} (f_{i-1} - c) \, \Delta t \right]$$

$$= \sum_{i=1}^{n} E_{t}^{\pi} \left[e^{-\int_{t}^{t_{i}} r(s) \, ds} \left(\frac{1}{P(t_{i-1}, t_{i})} - (1 + c\Delta t) \right) \right]$$

$$= \sum_{i=1}^{n} \left[P(t, t_{i-1}) - (1 + c\Delta t) \times P(t, t_{i}) \right]$$

$$= P(t, t_{0}) - P(t, t_{n}) - c\Delta t \sum_{i=1}^{n} P(t, t_{i}).$$

Interest Rate Swaps (concluded)

- So a swap can be replicated as a portfolio of bonds.
- In fact, it can be priced by simple present value calculations.

Swap Rate

• The swap rate, which gives the swap zero value, equals

$$S_n(t) \equiv \frac{P(t, t_0) - P(t, t_n)}{\sum_{i=1}^n P(t, t_i) \,\Delta t}.$$
 (92)

- The swap rate is the fixed rate that equates the present values of the fixed payments and the floating payments.
- For an ordinary swap, $P(t, t_0) = 1$.

The Term Structure Equation

- Let us start with the zero-coupon bonds and the money market account.
- Let the zero-coupon bond price P(r, t, T) follow

$$\frac{dP}{P} = \mu_p \, dt + \sigma_p \, dW.$$

• Suppose an investor at time t shorts one unit of a bond maturing at time s_1 and at the same time buys α units of a bond maturing at time s_2 .

• The net wealth change follows

 $-dP(r,t,s_1) + \alpha \, dP(r,t,s_2)$

$$= (-P(r,t,s_1) \mu_p(r,t,s_1) + \alpha P(r,t,s_2) \mu_p(r,t,s_2)) dt + (-P(r,t,s_1) \sigma_p(r,t,s_1) + \alpha P(r,t,s_2) \sigma_p(r,t,s_2)) dW.$$

• Pick

$$\alpha \equiv \frac{P(r,t,s_1) \,\sigma_p(r,t,s_1)}{P(r,t,s_2) \,\sigma_p(r,t,s_2)}$$

• Then the net wealth has no volatility and must earn the riskless return:

$$\frac{-P(r,t,s_1)\,\mu_p(r,t,s_1) + \alpha P(r,t,s_2)\,\mu_p(r,t,s_2)}{-P(r,t,s_1) + \alpha P(r,t,s_2)} = r.$$

• Simplify the above to obtain

$$\frac{\sigma_p(r,t,s_1)\,\mu_p(r,t,s_2) - \sigma_p(r,t,s_2)\,\mu_p(r,t,s_1)}{\sigma_p(r,t,s_1) - \sigma_p(r,t,s_2)} = r.$$

• This becomes

$$\frac{\mu_p(r,t,s_2) - r}{\sigma_p(r,t,s_2)} = \frac{\mu_p(r,t,s_1) - r}{\sigma_p(r,t,s_1)}$$

after rearrangement.

• Since the above equality holds for any s_1 and s_2 ,

$$\frac{\mu_p(r,t,s) - r}{\sigma_p(r,t,s)} \equiv \lambda(r,t) \tag{93}$$

for some λ independent of the bond maturity s.

- As $\mu_p = r + \lambda \sigma_p$, all assets are expected to appreciate at a rate equal to the sum of the short rate and a constant times the asset's volatility.
- The term $\lambda(r, t)$ is called the market price of risk.
- The market price of risk must be the same for all bonds to preclude arbitrage opportunities.

- Assume a Markovian short rate model, $dr = \mu(r, t) dt + \sigma(r, t) dW.$
- Then the bond price process is also Markovian.
- By Eq. (14.15) on p. 202 in the text,

$$\mu_p = \left(-\frac{\partial P}{\partial T} + \mu(r,t)\frac{\partial P}{\partial r} + \frac{\sigma(r,t)^2}{2}\frac{\partial^2 P}{\partial r^2}\right)/P, \qquad (94)$$
$$\sigma_p = \left(\sigma(r,t)\frac{\partial P}{\partial r}\right)/P, \qquad (94')$$

subject to $P(\cdot, T, T) = 1$.

• Substitute μ_p and σ_p into Eq. (93) on p. 849 to obtain

$$-\frac{\partial P}{\partial T} + \left[\mu(r,t) - \lambda(r,t)\,\sigma(r,t)\right]\frac{\partial P}{\partial r} + \frac{1}{2}\,\sigma(r,t)^2\,\frac{\partial^2 P}{\partial r^2} = rP.$$
(95)

- This is called the term structure equation.
- Once P is available, the spot rate curve emerges via

$$r(t,T) = -\frac{\ln P(t,T)}{T-t}.$$

• Equation (95) applies to all interest rate derivatives, the difference being the terminal and the boundary conditions.

The Binomial Model

- The analytical framework can be nicely illustrated with the binomial model.
- Suppose the bond price P can move with probability q to Pu and probability 1-q to Pd, where u > d:

The Binomial Model (continued)

• Over the period, the bond's expected rate of return is

$$\widehat{\mu} \equiv \frac{qPu + (1-q)Pd}{P} - 1 = qu + (1-q)d - 1.$$
(96)

• The variance of that return rate is

$$\widehat{\sigma}^2 \equiv q(1-q)(u-d)^2. \tag{97}$$

- The bond whose maturity is only one period away will move from a price of 1/(1+r) to its par value \$1.
- This is the money market account modeled by the short rate.

The Binomial Model (continued)

- The market price of risk is defined as $\lambda \equiv (\hat{\mu} r)/\hat{\sigma}$.
- As in the continuous-time case, it can be shown that λ is independent of the maturity of the bond (see text).

The Binomial Model (concluded)

• Now change the probability from q to

$$p \equiv q - \lambda \sqrt{q(1-q)} = \frac{(1+r) - d}{u - d},$$
 (98)

which is independent of bond maturity and q. - Recall the BOPM.

• The bond's expected rate of return becomes

$$\frac{pPu + (1-p)Pd}{P} - 1 = pu + (1-p)d - 1 = r.$$

• The local expectations theory hence holds under the new probability measure *p*.

Numerical Examples

• Assume this spot rate curve:

Year	1	2
Spot rate	4%	5%

• Assume the one-year rate (short rate) can move up to 8% or down to 2% after a year:

Numerical Examples (continued)

- No real-world probabilities are specified.
- The prices of one- and two-year zero-coupon bonds are, respectively,

$$100/1.04 = 96.154, 100/(1.05)^2 = 90.703.$$

• They follow the binomial processes on p. 858.

Numerical Examples (continued)

- The pricing of derivatives can be simplified by assuming investors are risk-neutral.
- Suppose all securities have the same expected one-period rate of return, the riskless rate.
- Then

$$(1-p) \times \frac{92.593}{90.703} + p \times \frac{98.039}{90.703} - 1 = 4\%,$$

where p denotes the risk-neutral probability of an up move in rates.

Numerical Examples (concluded)

- Solving the equation leads to p = 0.319.
- Interest rate contingent claims can be priced under this probability.

Numerical Examples: Fixed-Income Options

• A one-year European call on the two-year zero with a \$95 strike price has the payoffs,

• To solve for the option value C, we replicate the call by a portfolio of x one-year and y two-year zeros.

Numerical Examples: Fixed-Income Options (continued)

• This leads to the simultaneous equations,

$$x \times 100 + y \times 92.593 = 0.000,$$

 $x \times 100 + y \times 98.039 = 3.039.$

- They give x = -0.5167 and y = 0.5580.
- Consequently,

$$C = x \times 96.154 + y \times 90.703 \approx 0.93$$

to prevent arbitrage.

Numerical Examples: Fixed-Income Options (continued)

- This price is derived without assuming any version of an expectations theory.
- Instead, the arbitrage-free price is derived by replication.
- The price of an interest rate contingent claim does not depend directly on the real-world probabilities.
- The dependence holds only indirectly via the current bond prices.

Numerical Examples: Fixed-Income Options (concluded)

- An equivalent method is to utilize risk-neutral pricing.
- The above call option is worth

$$C = \frac{(1-p) \times 0 + p \times 3.039}{1.04} \approx 0.93,$$

the same as before.

• This is not surprising, as arbitrage freedom and the existence of a risk-neutral economy are equivalent.

Numerical Examples: Futures and Forward Prices

• A one-year futures contract on the one-year rate has a payoff of 100 - r, where r is the one-year rate at maturity:

- As the futures price F is the expected future payoff (see text), $F = (1 p) \times 92 + p \times 98 = 93.914$.
- On the other hand, the forward price for a one-year forward contract on a one-year zero-coupon bond equals 90.703/96.154 = 94.331%.
- The forward price exceeds the futures price.

Numerical Examples: Mortgage-Backed Securities

- Consider a 5%-coupon, two-year mortgage-backed security without amortization, prepayments, and default risk.
- Its cash flow and price process are illustrated on p. 867.
- Its fair price is

$$M = \frac{(1-p) \times 102.222 + p \times 107.941}{1.04} = 100.045.$$

• Identical results could have been obtained via arbitrage considerations.

Numerical Examples: MBSs (continued)

- Suppose that the security can be prepaid at par.
- It will be prepaid only when its price is higher than par.
- Prepayment will hence occur only in the "down" state when the security is worth 102.941 (excluding coupon).
- The price therefore follows the process, 102.222 M 105
- The security is worth

$$M = \frac{(1-p) \times 102.222 + p \times 105}{1.04} = 99.142.$$
Numerical Examples: MBSs (continued)

- The cash flow of the principal-only (PO) strip comes from the mortgage's principal cash flow.
- The cash flow of the interest-only (IO) strip comes from the interest cash flow (p. 870(a)).
- Their prices hence follow the processes on p. 870(b).
- The fair prices are

PO =
$$\frac{(1-p) \times 92.593 + p \times 100}{1.04} = 91.304,$$

IO = $\frac{(1-p) \times 9.630 + p \times 5}{1.04} = 7.839.$

Numerical Examples: MBSs (continued)

- Suppose the mortgage is split into half floater and half inverse floater.
- Let the floater (FLT) receive the one-year rate.
- Then the inverse floater (INV) must have a coupon rate of

(10% - one-year rate)

to make the overall coupon rate 5%.

• Their cash flows as percentages of par and values are shown on p. 872.

Numerical Examples: MBSs (concluded)

- On p. 872, the floater's price in the up node, 104, is derived from 4 + (108/1.08).
- The inverse floater's price 100.444 is derived from 6 + (102/1.08).
- The current prices are

FLT =
$$\frac{1}{2} \times \frac{104}{1.04} = 50$$
,
INV = $\frac{1}{2} \times \frac{(1-p) \times 100.444 + p \times 106}{1.04} = 49.142$.
