Hedging

When Professors Scholes and Merton and I invested in warrants, Professor Merton lost the most money. And I lost the least. — Fischer Black (1938–1995)

Delta Hedge

- The delta (hedge ratio) of a derivative f is defined as $\Delta \equiv \partial f / \partial S$.
- Thus $\Delta f \approx \Delta \times \Delta S$ for relatively small changes in the stock price, ΔS .
- A delta-neutral portfolio is hedged in the sense that it is immunized against small changes in the stock price.
- A trading strategy that dynamically maintains a delta-neutral portfolio is called delta hedge.

Delta Hedge (concluded)

- Delta changes with the stock price.
- A delta hedge needs to be rebalanced periodically in order to maintain delta neutrality.
- In the limit where the portfolio is adjusted continuously, perfect hedge is achieved and the strategy becomes self-financing.

Implementing Delta Hedge

- We want to hedge N short derivatives.
- Assume the stock pays no dividends.
- The delta-neutral portfolio maintains $N \times \Delta$ shares of stock plus B borrowed dollars such that

 $-N \times f + N \times \Delta \times S - B = 0.$

- At next rebalancing point when the delta is Δ' , buy $N \times (\Delta' \Delta)$ shares to maintain $N \times \Delta'$ shares with a total borrowing of $B' = N \times \Delta' \times S' N \times f'$.
- Delta hedge is the discrete-time analog of the continuous-time limit and will rarely be self-financing.

Example

- A hedger is *short* 10,000 European calls.
- $\sigma = 30\%$ and r = 6%.
- This call's expiration is four weeks away, its strike price is \$50, and each call has a current value of f = 1.76791.
- As an option covers 100 shares of stock, N = 1,000,000.
- The trader adjusts the portfolio weekly.
- The calls are replicated well if the cumulative cost of trading *stock* is close to the call premium's FV.^a

^aThis example takes the replication viewpoint.

- As $\Delta = 0.538560$, $N \times \Delta = 538,560$ shares are purchased for a total cost of $538,560 \times 50 = 26,928,000$ dollars to make the portfolio delta-neutral.
- The trader finances the purchase by borrowing

$$B = N \times \Delta \times S - N \times f = 25,160,090$$

dollars net.^a

• The portfolio has zero net value now.

^aThis takes the hedging viewpoint — an alternative. See an exercise in the text.

- At 3 weeks to expiration, the stock price rises to \$51.
- The new call value is f' = 2.10580.
- So the portfolio is worth

$$-N \times f' + 538,560 \times 51 - Be^{0.06/52} = 171,622$$

before rebalancing.

- A delta hedge does not replicate the calls perfectly; it is not self-financing as \$171,622 can be withdrawn.
- The magnitude of the tracking error—the variation in the net portfolio value—can be mitigated if adjustments are made more frequently.
- In fact, the tracking error *over one rebalancing act* is positive about 68% of the time, but its expected value is essentially zero.^a
- It is furthermore proportional to vega.

^aBoyle and Emanuel (1980).

- In practice tracking errors will cease to decrease beyond a certain rebalancing frequency.
- With a higher delta $\Delta' = 0.640355$, the trader buys $N \times (\Delta' \Delta) = 101,795$ shares for \$5,191,545.
- The number of shares is increased to $N \times \Delta' = 640,355$.

• The cumulative cost is

 $26,928,000 \times e^{0.06/52} + 5,191,545 = 32,150,634.$

• The portfolio is again delta-neutral.

		Option		Change in	No. shares	Cost of	Cumulative
		value	Delta	delta	bought	shares	cost
au	S	f	Δ		N imes (5)	$(1) \times (6)$	FV(8') + (7)
	(1)	(2)	(3)	(5)	(6)	(7)	(8)
4	50	1.7679	0.53856		538,560	$26,\!928,\!000$	$26,\!928,\!000$
3	51	2.1058	0.64036	0.10180	$101,\!795$	$5,\!191,\!545$	$32,\!150,\!634$
2	53	3.3509	0.85578	0.21542	$215,\!425$	$11,\!417,\!525$	$43,\!605,\!277$
1	52	2.2427	0.83983	-0.01595	-15,955	$-829,\!660$	$42,\!825,\!960$
0	54	4.0000	1.00000	0.16017	$160,\!175$	$8,\!649,\!450$	$51,\!524,\!853$

The total number of shares is 1,000,000 at expiration (trading takes place at expiration, too).

Example (concluded)

- At expiration, the trader has 1,000,000 shares.
- They are exercised against by the in-the-money calls for \$50,000,000.
- The trader is left with an obligation of

51,524,853 - 50,000,000 = 1,524,853,

which represents the replication cost.

• Compared with the FV of the call premium,

 $1,767,910 \times e^{0.06 \times 4/52} = 1,776,088,$

the net gain is 1,776,088 - 1,524,853 = 251,235.

Tracking Error Revisited

- Define the dollar gamma as $S^2\Gamma$.
- The change in value of a delta-hedged *long* option position after a duration of Δt is proportional to the dollar gamma.
- It is about

$$(1/2)S^{2}\Gamma[(\Delta S/S)^{2} - \sigma^{2}\Delta t].$$

 $- (\Delta S/S)^2$ is called the daily realized variance.

Tracking Error Revisited (continued)

• Let the rebalancing times be t_1, t_2, \ldots, t_n .

• Let
$$\Delta S_i = S_{i+1} - S_i$$
.

• The total tracking error at expiration is about

$$\sum_{i=0}^{n-1} e^{r(T-t_i)} \frac{S_i^2 \Gamma_i}{2} \left[\left(\frac{\Delta S_i}{S_i} \right)^2 - \sigma^2 \Delta t \right],$$

• The tracking error is path dependent.

Tracking Error Revisited (concluded) a

- The tracking error ϵ_n over *n* rebalancing acts (such as 251,235 on p. 549) has about the same probability of being positive as being negative.
- Subject to certain regularity conditions, the root-mean-square tracking error $\sqrt{E[\epsilon_n^2]}$ is $O(1/\sqrt{n})$.^b
- The root-mean-square tracking error increases with σ at first and then decreases.

^aBertsimas, Kogan, and Lo (2000). ^bSee also Grannan and Swindle (1996).

Delta-Gamma Hedge

- Delta hedge is based on the first-order approximation to changes in the derivative price, Δf , due to changes in the stock price, ΔS .
- When ΔS is not small, the second-order term, gamma $\Gamma \equiv \partial^2 f / \partial S^2$, helps (theoretically).
- A delta-gamma hedge is a delta hedge that maintains zero portfolio gamma, or gamma neutrality.
- To meet this extra condition, one more security needs to be brought in.

Delta-Gamma Hedge (concluded)

- Suppose we want to hedge short calls as before.
- A hedging call f_2 is brought in.
- To set up a delta-gamma hedge, we solve

$$-N \times f + n_1 \times S + n_2 \times f_2 - B = 0 \quad \text{(self-financing)},$$

$$-N \times \Delta + n_1 + n_2 \times \Delta_2 - 0 = 0 \quad \text{(delta neutrality)},$$

$$-N \times \Gamma + 0 + n_2 \times \Gamma_2 - 0 = 0 \quad \text{(gamma neutrality)},$$

for n_1, n_2 , and B.

- The gammas of the stock and bond are 0.

Other Hedges

- If volatility changes, delta-gamma hedge may not work well.
- An enhancement is the delta-gamma-vega hedge, which also maintains vega zero portfolio vega.
- To accomplish this, one more security has to be brought into the process.
- In practice, delta-vega hedge, which may not maintain gamma neutrality, performs better than delta hedge.

I love a tree more than a man. — Ludwig van Beethoven (1770–1827)

And though the holes were rather small, they had to count them all. — The Beatles, A Day in the Life (1967)

The Combinatorial Method

- The combinatorial method can often cut the running time by an order of magnitude.
- The basic paradigm is to count the number of admissible paths that lead from the root to any terminal node.
- We first used this method in the linear-time algorithm for standard European option pricing on p. 238.
- We will now apply it to price barrier options.

The Reflection $\mathsf{Principle}^{\mathrm{a}}$

- Imagine a particle at position (0, -a) on the integral lattice that is to reach (n, -b).
- Without loss of generality, assume a > 0 and $b \ge 0$.
- This particle's movement:

$$(i,j) \underbrace{ \begin{array}{c} \bullet \\ (i+1,j+1) & \text{up move } S \to Su \\ \bullet \\ (i+1,j-1) & \text{down move } S \to Sd \end{array} }$$

• How many paths touch the x axis?

 $^{\mathrm{a}}\mathrm{Andr\acute{e}}$ (1887).

The Reflection Principle (continued)

- For a path from (0, -a) to (n, -b) that touches the x axis, let J denote the first point this happens.
- Reflect the portion of the path from (0, -a) to J.
- A path from $(0, \mathbf{a})$ to $(n, -\mathbf{b})$ is constructed.
- It also hits the x axis at J for the first time.
- The one-to-one mapping shows the number of paths from (0, -a) to (n, -b) that touch the x axis equals the number of paths from (0, a) to (n, -b).

The Reflection Principle (concluded)

- A path of this kind has (n + b + a)/2 down moves and (n b a)/2 up moves.
- Hence there are

$$\binom{n}{\frac{n+a+b}{2}}\tag{59}$$

such paths for even n + a + b.

- Convention: $\binom{n}{k} = 0$ for k < 0 or k > n.

Pricing Barrier Options (Lyuu, 1998)

- Focus on the down-and-in call with barrier H < X.
- Assume H < S without loss of generality.
- Define

$$a \equiv \left[\frac{\ln\left(X/\left(Sd^{n}\right)\right)}{\ln\left(u/d\right)}\right] = \left[\frac{\ln(X/S)}{2\sigma\sqrt{\Delta t}} + \frac{n}{2}\right],$$
$$h \equiv \left[\frac{\ln\left(H/\left(Sd^{n}\right)\right)}{\ln\left(u/d\right)}\right] = \left[\frac{\ln(H/S)}{2\sigma\sqrt{\Delta t}} + \frac{n}{2}\right].$$

- h is such that $\tilde{H} \equiv Su^h d^{n-h}$ is the *terminal* price that is closest to, but does not exceed H.
- a is such that $\tilde{X} \equiv Su^a d^{n-a}$ is the terminal price that is closest to, but is not exceeded by X.

Pricing Barrier Options (continued)

- The true barrier is replaced by the effective barrier \tilde{H} in the binomial model.
- A process with *n* moves hence ends up in the money if and only if the number of up moves is at least *a*.
- The price $Su^k d^{n-k}$ is at a distance of 2k from the lowest possible price Sd^n on the binomial tree.

$$Su^{k}d^{n-k} = Sd^{-k}d^{n-k} = Sd^{n-2k}.$$
 (60)

Pricing Barrier Options (continued)

- The number of paths from S to the terminal price $Su^{j}d^{n-j}$ is $\binom{n}{j}$, each with probability $p^{j}(1-p)^{n-j}$.
- With reference to p. 565, the reflection principle can be applied with *a* = n 2h and *b* = 2j 2h in Eq. (59) on p. 562 by treating the S line as the x axis.
- Therefore,

$$\binom{n}{\frac{n+(n-2h)+(2j-2h)}{2}} = \binom{n}{n-2h+j}$$

paths hit \tilde{H} in the process for $h \leq n/2$.

Pricing Barrier Options (concluded)

• The terminal price $Su^{j}d^{n-j}$ is reached by a path that hits the effective barrier with probability

$$\binom{n}{n-2h+j}p^j(1-p)^{n-j}.$$

• The option value equals

$$\frac{\sum_{j=a}^{2h} \binom{n}{n-2h+j} p^j (1-p)^{n-j} \left(S u^j d^{n-j} - X\right)}{R^n}.$$
 (61)

 $-R \equiv e^{r\tau/n}$ is the riskless return per period.

• It implies a linear-time algorithm.

Convergence of BOPM

- Equation (61) results in the sawtooth-like convergence shown on p. 327.
- The reasons are not hard to see.
- The true barrier most likely does not equal the effective barrier.
- The same holds for the strike price and the effective strike price.
- The issue of the strike price is less critical.
- But the issue of the barrier is not negligible.

Convergence of BOPM (continued)

- Convergence is actually good if we limit n to certain values—191, for example.
- These values make the true barrier coincide with or just above one of the stock price levels, that is,

$$H \approx S d^j = S e^{-j\sigma \sqrt{\tau/n}}$$

for some integer j.

• The preferred n's are thus

$$n = \left\lfloor \frac{\tau}{\left(\ln(S/H)/(j\sigma)\right)^2} \right\rfloor, \quad j = 1, 2, 3, \dots$$

Convergence of BOPM (continued)

- There is only one minor technicality left.
- We picked the effective barrier to be one of the n+1 possible terminal stock prices.
- However, the effective barrier above, Sd^{j} , corresponds to a terminal stock price only when n - j is even.^a
- To close this gap, we decrement n by one, if necessary, to make n j an even number.

^aThis is because j = n - 2k for some k by Eq. (60) on p. 564. Of course we could have adopted the form Sd^j $(-n \leq j \leq n)$ for the effective barrier.

Convergence of BOPM (concluded)

• The preferred n's are now

$$n = \begin{cases} \ell & \text{if } \ell - j \text{ is even} \\ \ell - 1 & \text{otherwise} \end{cases},$$

 $j = 1, 2, 3, \dots$, where

$$\ell \equiv \left\lfloor \frac{\tau}{\left(\ln(S/H)/(j\sigma)\right)^2} \right\rfloor$$

• Evaluate pricing formula (61) on p. 567 only with the *n*'s above.

Practical Implications

- Now that barrier options can be efficiently priced, we can afford to pick very large n's (p. 574).
- This has profound consequences.

O2010 Prof. Yuh-Dauh Lyuu, National Taiwan University

Practical Implications (concluded)

• Pricing is prohibitively time consuming when $S \approx H$ because $n \sim 1/\ln^2(S/H)$.

- This is called the barrier-too-close problem.

- This observation is indeed true of standard quadratic-time binomial tree algorithms.
- But it no longer applies to linear-time algorithms (see p. 576).
- In fact, this model is O(1/n) convergent.^a

^aLin (**R95221010**) (2008).

Trinomial Tree

- Set up a trinomial approximation to the geometric Brownian motion $dS/S = r dt + \sigma dW$.^a
- The three stock prices at time Δt are S, Su, and Sd, where ud = 1.
- Impose the matching of mean and that of variance:

$$1 = p_{u} + p_{m} + p_{d},$$

$$SM \equiv (p_{u}u + p_{m} + (p_{d}/u))S,$$

$$S^{2}V \equiv p_{u}(Su - SM)^{2} + p_{m}(S - SM)^{2} + p_{d}(Sd - SM)^{2}.$$

^aBoyle (1988).

• Above,

$$M \equiv e^{r\Delta t},$$
$$V \equiv M^2(e^{\sigma^2 \Delta t} - 1),$$

by Eqs. (18) on p. 151.

Trinomial Tree (continued)

• Use linear algebra to verify that

$$p_{u} = \frac{u \left(V + M^{2} - M\right) - (M - 1)}{(u - 1) (u^{2} - 1)},$$

$$p_{d} = \frac{u^{2} \left(V + M^{2} - M\right) - u^{3} (M - 1)}{(u - 1) (u^{2} - 1)}.$$

- In practice, must make sure the probabilities lie between 0 and 1.
- Countless variations.

Trinomial Tree (concluded)

- Use $u = e^{\lambda \sigma \sqrt{\Delta t}}$, where $\lambda \ge 1$ is a tunable parameter.
- Then

$$p_u \rightarrow \frac{1}{2\lambda^2} + \frac{(r+\sigma^2)\sqrt{\Delta t}}{2\lambda\sigma},$$

 $p_d \rightarrow \frac{1}{2\lambda^2} - \frac{(r-2\sigma^2)\sqrt{\Delta t}}{2\lambda\sigma}.$

• A nice choice for λ is $\sqrt{\pi/2}$.^a

^aOmberg (1988).

Barrier Options Revisited

- BOPM introduces a specification error by replacing the barrier with a nonidentical effective barrier.
- The trinomial model solves the problem by adjusting λ so that the barrier is hit exactly.^a
- It takes

$$h = \frac{\ln(S/H)}{\lambda \sigma \sqrt{\Delta t}}$$

consecutive down moves to go from S to H if h is an integer, which is easy to achieve by adjusting λ .

- This is because $Se^{-h\lambda\sigma\sqrt{\Delta t}} = H$.

^aRitchken (1995).

Barrier Options Revisited (continued)

- Typically, we find the smallest $\lambda \ge 1$ such that h is an integer.
- That is, we find the largest integer $j \ge 1$ that satisfies $\frac{\ln(S/H)}{j\sigma\sqrt{\Delta t}} \ge 1$ and then let

$$\lambda = \frac{\ln(S/H)}{j\sigma\sqrt{\Delta t}}.$$

- Such a λ may not exist for very small *n*'s.
- This is not hard to check.
- This done, one of the layers of the trinomial tree coincides with the barrier.

Barrier Options Revisited (concluded)

• The following probabilities may be used,

$$p_u = \frac{1}{2\lambda^2} + \frac{\mu'\sqrt{\Delta t}}{2\lambda\sigma},$$

$$p_m = 1 - \frac{1}{\lambda^2},$$

$$p_d = \frac{1}{2\lambda^2} - \frac{\mu'\sqrt{\Delta t}}{2\lambda\sigma}.$$

$$-\mu' \equiv r - \sigma^2/2.$$

Algorithms Comparison^a

- So which algorithm is better, binomial or trinomial?
- Algorithms are often compared based on the *n* value at which they converge.
 - The one with the smallest n wins.
- So giraffes are faster than cheetahs because they take fewer strides to travel the same distance!
- Performance must be based on actual running times.

^aLyuu (1998).

Algorithms Comparison (concluded)

- Pages 327 and 585 show the trinomial model converges at a smaller n than BOPM.
- It is in this sense when people say trinomial models converge faster than binomial ones.
- But is the trinomial model better then?
- The linear-time binomial tree algorithm actually performs better than the trinomial one.
- See the next page, expanded from p. 574.

n	Combinatorial	method	Trinomial tree algorithm		
	Value	Time	Value	Time

5472	5.660122	68.70			
6177	5.659981	76.70			

(All times in milliseconds.)

Double-Barrier Options

- Double-barrier options are barrier options with two barriers L < H.
- Assume L < S < H.
- The binomial model produces oscillating option values (see plot on next page).^a

^aChao (**R86526053**) (1999); Dai (**R86526008**, **D8852600**) and Lyuu (2005).

Double-Barrier Knock-Out Options

- We knew how to pick the λ so that one of the layers of the trinomial tree coincides with one barrier, say H.
- This choice, however, does not guarantee that the other barrier, *L*, is also hit.
- One way to handle this problem is to lower the layer of the tree just above L to coincide with L.^a
 - More general ways to make the trinomial model hit both barriers are available.^b

^aRitchken (1995).

^bHsu (R7526001) and Lyuu (2006). Dai (R86526008, D8852600) and Lyuu (2006) combine binomial and trinomial trees to derive an O(n)-time algorithm for double-barrier options (see pp. 596ff).

Double-Barrier Knock-Out Options (continued)

- The probabilities of the nodes on the layer above L must be adjusted.
- Let ℓ be the positive integer such that

$$Sd^{\ell+1} < L < Sd^{\ell}.$$

• Hence the layer of the tree just above L has price Sd^{ℓ} .

Double-Barrier Knock-Out Options (concluded)

• Define $\gamma > 1$ as the number satisfying

$$L = S d^{\ell - 1} e^{-\gamma \lambda \sigma \sqrt{\Delta t}}$$

- The prices between the barriers are

$$L, Sd^{\ell-1}, \dots, Sd^2, Sd, S, Su, Su^2, \dots, Su^{h-1}, Su^h = H.$$

• The probabilities for the nodes with price equal to $Sd^{\ell-1}$ are

$$p'_u = \frac{b + a\gamma}{1 + \gamma}, \quad p'_d = \frac{b - a}{\gamma + \gamma^2}, \text{ and } p'_m = 1 - p'_u - p'_d,$$

where $a \equiv \mu' \sqrt{\Delta t} / (\lambda \sigma)$ and $b \equiv 1/\lambda^2$.

The Binomial-Trinomial Tree

- Embedding a trinomial structure to a binomial tree can lead to improved convergence and efficiency.^a
- The resulting tree is called the binomial-trinomial tree.
- Suppose the binomial tree is built with Δt as the duration of one period.
- Node X at time t needs to pick three nodes on the binomial tree at time $t + \Delta t'$ as its successor nodes.

 $-\Delta t \le \Delta t' < 2\Delta t.$

^aDai (R86526008, D8852600) and Lyuu (2006, 2008).

- These three nodes should guarantee:
 - 1. The mean and variance of the stock price are matched.
 - 2. The branching probabilities are between 0 and 1.
- Let S be the stock price at node X.
- Use s(z) to denote the stock price at node z.

• The expected value of the logarithmic return $\ln(S_{t+\Delta t'}/S)$ at time $t + \Delta t'$ equals

$$\mu \equiv \left(r - \sigma^2/2\right) \Delta t'. \tag{62}$$

• Its variance equals

$$\operatorname{Var} \equiv \sigma^2 \Delta t'. \tag{63}$$

- Let node B be the node whose logarithmic return $\hat{\mu} \equiv \ln(s(B)/S)$ is closest to μ among all the nodes on the binomial tree at time $t + \Delta t'$.
- The middle branch from node X will end at node B.
- The two nodes A and C, which bracket node B, are the destinations of the other two branches from node X.
- Recall that adjacent nodes on the binomial tree are spaced at $2\sigma\sqrt{\Delta t}$ apart.
- See the figure on p. 600 for illustration.

- The three branching probabilities from node X are obtained through matching the mean and variance of the logarithmic return $\ln(S_{t+\Delta t'}/S)$.
- Let $\hat{\mu} \equiv \ln (s(B)/S)$ be the logarithmic return of the middle node B.
- Also, let α, β, and γ be the differences between μ and the logarithmic returns ln(s(Z)/S) of nodes Z = A, B, C, in that order.

• In other words,

$$\alpha \equiv \hat{\mu} + 2\sigma\sqrt{\Delta t} - \mu = \beta + 2\sigma\sqrt{\Delta t}, \qquad (64)$$

$$\beta \equiv \hat{\mu} - \mu, \tag{65}$$

$$\gamma \equiv \hat{\mu} - 2\sigma\sqrt{\Delta t} - \mu = \beta - 2\sigma\sqrt{\Delta t} \,. \tag{66}$$

• The three branching probabilities p_u, p_m, p_d then satisfy

$$p_u \alpha + p_m \beta + p_d \gamma = 0, \qquad (67)$$

$$p_u \alpha^2 + p_m \beta^2 + p_d \gamma^2 = \text{Var}, \qquad (68)$$

$$p_u + p_m + p_d = 1.$$
 (69)

- Equation (67) matches the mean (62) of the logarithmic return $\ln(S_{t+\Delta t'}/S)$ on p. 598.
- Equation (68) matches its variance (63) on p. 598.
- The three probabilities can be proved to lie between 0 and 1.

Pricing Barrier Options

- Consider a double-barrier option with two barriers Land H, where L < S < H.
- We need to make each barrier coincide with a layer of the binomial tree for better convergence.
- This means choosing a Δt such that

$$\kappa \equiv \frac{\ln(H/L)}{2\sigma\sqrt{\Delta t}}$$

is a positive integer.

- The distance between two adjacent nodes such as nodes Y and Z in the figure on p. 605 is $2\sigma\sqrt{\Delta t}$.

Pricing Barrier Options (continued)

- Suppose that the goal is a tree with about m periods.
- Suppose we pick $\Delta \tau \equiv T/m$ for the length of each period.
- There is no guarantee that $\frac{\ln(H/L)}{2\sigma\sqrt{\Delta\tau}}$ is an integer.
- So we pick a Δt that is close to, but does not exceed, $\Delta \tau$ and makes $\frac{\ln(H/L)}{2\sigma\sqrt{\Delta t}}$ an integer.
- Specifically, we select

$$\Delta t = \left(\frac{\ln(H/L)}{2\kappa\sigma}\right)^2,$$

where
$$\kappa = \left[\frac{\ln(H/L)}{2\sigma\sqrt{\Delta\tau}}\right]$$
.

Pricing Barrier Options (continued)

- We now proceed to build the binomial-trinomial tree.
- Start with the binomial part.
- Lay out the nodes from the low barrier L upward and downward.
- Automatically, a layer coincides with the high barrier H.
- It is unlikely that Δt divides T, however.
- As a consequence, the position at time 0 and with logarithmic return $\ln(S/S) = 0$ is not occupied by a binomial node to serve as the root node.

Pricing Barrier Options (continued)

- The binomial-trinomial structure can address this problem as follows.
- Between time 0 and time T, the binomial tree spans $T/\Delta t$ periods.
- Keep only the last $\lfloor T/\Delta t \rfloor 1$ periods and let the first period have a duration equal to

$$\Delta t' = T - \left(\left\lfloor \frac{T}{\Delta t} \right\rfloor - 1 \right) \Delta t.$$

- Then these $\lfloor T/\Delta t \rfloor$ periods span T years.
- It is easy to verify that $\Delta t \leq \Delta t' < 2\Delta t$.
Pricing Barrier Options (continued)

- Start with the root node at time 0 and at a price with logarithmic return $\ln(S/S) = 0$.
- Find the three nodes on the binomial tree at time $\Delta t'$ as described earlier.
- Calculate the three branching probabilities to them.
- Grow the binomial tree from these three nodes until time T to obtain a binomial-trinomial tree with $\lfloor T/\Delta t \rfloor$ periods.
- See the figure on p. 605 for illustration.

Pricing Barrier Options (continued)

- Now the binomial-trinomial tree can be used to price double-barrier options by backward induction.
- That takes quadratic time.
- But we know a linear-time algorithm exists for double-barrier options on the binomial tree (see text).
- Apply that algorithm to price the double-barrier option's prices at the three nodes at time $\Delta t'$.

– That is, nodes A, B, and C on p. 605.

- Then calculate their expected discounted value for the root node.
- The overall running time is only linear.

Pricing Barrier Options (continued)

- Binomial trees have troubles with pricing barrier options (see p. 327 and p. 595).
- Even compared with the much better trinomial tree, the binomial-trinomial tree converges faster and smoother (see p. 612).

The thin line denotes the double-barrier option prices computed by the trinomial tree against the running time in seconds (such as point A). The thick line denotes those computed by the binomial-trinomial tree (such as point B).
