

Euler Approximation

- The following approximation follows from Eq. (56),

$$\begin{aligned} \hat{X}(t_{n+1}) \\ = \hat{X}(t_n) + a(\hat{X}(t_n), t_n) \Delta t + b(\hat{X}(t_n), t_n) \Delta W(t_n), \end{aligned} \tag{57}$$

where $t_n \equiv n\Delta t$.

- It is called the Euler or Euler-Maruyama method.
- Recall that $\Delta W(t_n)$ should be interpreted as $W(t_{n+1}) - W(t_n)$, not $W(t_n) - W(t_{n-1})$.
- Under mild conditions, $\hat{X}(t_n)$ converges to $X(t_n)$.

More Discrete Approximations

- Under fairly loose regularity conditions, Eq. (57) on p. 532 can be replaced by

$$\begin{aligned}\hat{X}(t_{n+1}) \\ = \hat{X}(t_n) + a(\hat{X}(t_n), t_n) \Delta t + b(\hat{X}(t_n), t_n) \sqrt{\Delta t} Y(t_n).\end{aligned}$$

- $Y(t_0), Y(t_1), \dots$ are independent and identically distributed with zero mean and unit variance.

More Discrete Approximations (concluded)

- An even simpler discrete approximation scheme:

$$\begin{aligned}\widehat{X}(t_{n+1}) \\ = \widehat{X}(t_n) + a(\widehat{X}(t_n), t_n) \Delta t + b(\widehat{X}(t_n), t_n) \sqrt{\Delta t} \xi.\end{aligned}$$

- $\text{Prob}[\xi = 1] = \text{Prob}[\xi = -1] = 1/2$.
- Note that $E[\xi] = 0$ and $\text{Var}[\xi] = 1$.
- This is a binomial model.
- As Δt goes to zero, \widehat{X} converges to X .

Trading and the Ito Integral

- Consider an Ito process $d\mathbf{S}_t = \mu_t dt + \sigma_t dW_t$.
 - \mathbf{S}_t is the vector of security prices at time t .
- Let ϕ_t be a trading strategy denoting the quantity of each type of security held at time t .
 - Hence the stochastic process $\phi_t \mathbf{S}_t$ is the value of the portfolio ϕ_t at time t .
- $\phi_t d\mathbf{S}_t \equiv \phi_t(\mu_t dt + \sigma_t dW_t)$ represents the change in the value from security price changes occurring at time t .

Trading and the Ito Integral (concluded)

- The equivalent Ito integral,

$$G_T(\phi) \equiv \int_0^T \phi_t d\mathbf{S}_t = \int_0^T \phi_t \mu_t dt + \int_0^T \phi_t \sigma_t dW_t,$$

measures the gains realized by the trading strategy over the period $[0, T]$.

Ito's Lemma

A smooth function of an Ito process is itself an Ito process.

Theorem 19 *Suppose $f : R \rightarrow R$ is twice continuously differentiable and $dX = a_t dt + b_t dW$. Then $f(X)$ is the Ito process,*

$$\begin{aligned} f(X_t) \\ = & f(X_0) + \int_0^t f'(X_s) a_s ds + \int_0^t f'(X_s) b_s dW \\ & + \frac{1}{2} \int_0^t f''(X_s) b_s^2 ds \end{aligned}$$

for $t \geq 0$.

Ito's Lemma (continued)

- In differential form, Ito's lemma becomes

$$df(X) = f'(X) a dt + f'(X) b dW + \frac{1}{2} f''(X) b^2 dt. \quad (58)$$

- Compared with calculus, the interesting part is the third term on the right-hand side.
- A convenient formulation of Ito's lemma is

$$df(X) = f'(X) dX + \frac{1}{2} f''(X)(dX)^2.$$

Ito's Lemma (continued)

- We are supposed to multiply out $(dX)^2 = (a dt + b dW)^2$ symbolically according to

\times	dW	dt
dW	dt	0
dt	0	0

- The $(dW)^2 = dt$ entry is justified by a known result.
- Hence $(dX)^2 = (a dt + b dW)^2 = b^2 dt$.
- This form is easy to remember because of its similarity to the Taylor expansion.

Ito's Lemma (continued)

Theorem 20 (Higher-Dimensional Ito's Lemma) *Let W_1, W_2, \dots, W_n be independent Wiener processes and $X \equiv (X_1, X_2, \dots, X_m)$ be a vector process. Suppose $f : R^m \rightarrow R$ is twice continuously differentiable and X_i is an Ito process with $dX_i = a_i dt + \sum_{j=1}^n b_{ij} dW_j$. Then $df(X)$ is an Ito process with the differential,*

$$df(X) = \sum_{i=1}^m f_i(X) dX_i + \frac{1}{2} \sum_{i=1}^m \sum_{k=1}^m f_{ik}(X) dX_i dX_k,$$

where $f_i \equiv \partial f / \partial X_i$ and $f_{ik} \equiv \partial^2 f / \partial X_i \partial X_k$.

Ito's Lemma (continued)

- The multiplication table for Theorem 20 is

\times	dW_i	dt
dW_k	$\delta_{ik} dt$	0
dt	0	0

in which

$$\delta_{ik} = \begin{cases} 1 & \text{if } i = k, \\ 0 & \text{otherwise.} \end{cases}$$

Ito's Lemma (continued)

- In applying the higher-dimensional Ito's lemma, usually one of the variables, say X_1 , is time t and $dX_1 = dt$.
- In this case, $b_{1j} = 0$ for all j and $a_1 = 1$.
- As an example, let

$$dX_t = a_t dt + b_t dW_t.$$

- Consider the process $f(X_t, t)$.

Ito's Lemma (continued)

- Then

$$\begin{aligned} df &= \frac{\partial f}{\partial X_t} dX_t + \frac{\partial f}{\partial t} dt + \frac{1}{2} \frac{\partial^2 f}{\partial X_t^2} (dX_t)^2 \\ &= \frac{\partial f}{\partial X_t} (a_t dt + b_t dW_t) + \frac{\partial f}{\partial t} dt \\ &\quad + \frac{1}{2} \frac{\partial^2 f}{\partial X_t^2} (a_t dt + b_t dW_t)^2 \\ &= \left(\frac{\partial f}{\partial X_t} a_t + \frac{\partial f}{\partial t} + \frac{1}{2} \frac{\partial^2 f}{\partial X_t^2} b_t^2 \right) dt \\ &\quad + \frac{\partial f}{\partial X_t} b_t dW_t. \end{aligned}$$

Ito's Lemma (continued)

Theorem 21 (Alternative Ito's Lemma) *Let W_1, W_2, \dots, W_m be Wiener processes and $X \equiv (X_1, X_2, \dots, X_m)$ be a vector process. Suppose $f : R^m \rightarrow R$ is twice continuously differentiable and X_i is an Ito process with $dX_i = a_i dt + b_i dW_i$. Then $df(X)$ is the following Ito process,*

$$df(X) = \sum_{i=1}^m f_i(X) dX_i + \frac{1}{2} \sum_{i=1}^m \sum_{k=1}^m f_{ik}(X) dX_i dX_k.$$

Ito's Lemma (concluded)

- The multiplication table for Theorem 21 is

\times	dW_i	dt
dW_k	$\rho_{ik} dt$	0
dt	0	0

- Above, ρ_{ik} denotes the correlation between dW_i and dW_k .

Geometric Brownian Motion

- Consider geometric Brownian motion $Y(t) \equiv e^{X(t)}$
 - $X(t)$ is a (μ, σ) Brownian motion.
 - Hence $dX = \mu dt + \sigma dW$ by Eq. (53) on p. 508.
- Note that

$$\begin{aligned}\frac{\partial Y}{\partial X} &= Y, \\ \frac{\partial^2 Y}{\partial X^2} &= -Y.\end{aligned}$$

Geometric Brownian Motion (concluded)

- Ito's formula (58) on p. 538 implies

$$\begin{aligned}dY &= Y dX + (1/2) Y (dX)^2 \\&= Y (\mu dt + \sigma dW) + (1/2) Y (\mu dt + \sigma dW)^2 \\&= Y (\mu dt + \sigma dW) + (1/2) Y \sigma^2 dt.\end{aligned}$$

- Hence

$$\frac{dY}{Y} = (\mu + \sigma^2/2) dt + \sigma dW. \quad (59)$$

- The annualized *instantaneous* rate of return is $\mu + \sigma^2/2$ (not μ).

Product of Geometric Brownian Motion Processes

- Let

$$\begin{aligned}dY/Y &= a dt + b dW_Y, \\dZ/Z &= f dt + g dW_Z.\end{aligned}$$

- Consider the Ito process $U \equiv YZ$.
- Apply Ito's lemma (Theorem 21 on p. 544):

$$\begin{aligned}dU &= Z dY + Y dZ + dY dZ \\&= ZY(a dt + b dW_Y) + YZ(f dt + g dW_Z) \\&\quad + YZ(a dt + b dW_Y)(f dt + g dW_Z) \\&= U(a + f + bg\rho) dt + Ub dW_Y + Ug dW_Z.\end{aligned}$$

Product of Geometric Brownian Motion Processes (continued)

- The product of two (or more) correlated geometric Brownian motion processes thus remains geometric Brownian motion.
- Note that

$$Y = \exp \left[(a - b^2/2) dt + b dW_Y \right],$$

$$Z = \exp \left[(f - g^2/2) dt + g dW_Z \right],$$

$$U = \exp \left[(a + f - (b^2 + g^2)/2) dt + b dW_Y + g dW_Z \right].$$

- There is no $bg\rho$ term in U !

Product of Geometric Brownian Motion Processes (concluded)

- $\ln U$ is Brownian motion with a mean equal to the sum of the means of $\ln Y$ and $\ln Z$.
- This holds even if Y and Z are correlated.
- Finally, $\ln Y$ and $\ln Z$ have correlation ρ .

Quotients of Geometric Brownian Motion Processes

- Suppose Y and Z are drawn from p. 548.
- Let $U \equiv Y/Z$.
- We now show that^a

$$\frac{dU}{U} = (a - f + g^2 - bg\rho) dt + b dW_Y - g dW_Z. \quad (60)$$

- Keep in mind that dW_Y and dW_Z have correlation ρ .

^aExercise 14.3.6 of the textbook is erroneous.

Quotients of Geometric Brownian Motion Processes (concluded)

- The multidimensional Ito's lemma (Theorem 21 on p. 544) can be employed to show that

$$\begin{aligned} dU &= (1/Z) dY - (Y/Z^2) dZ - (1/Z^2) dY dZ + (Y/Z^3) (dZ)^2 \\ &= (1/Z)(aY dt + bY dW_Y) - (Y/Z^2)(fZ dt + gZ dW_Z) \\ &\quad - (1/Z^2)(bgYZ\rho dt) + (Y/Z^3)(g^2 Z^2 dt) \\ &= U(a dt + b dW_Y) - U(f dt + g dW_Z) \\ &\quad - U(bg\rho dt) + U(g^2 dt) \\ &= U(a - f + g^2 - bg\rho) dt + Ub dW_Y - Ug dW_Z. \end{aligned}$$

Forward Price

- Suppose S follows

$$\frac{dS}{S} = \mu dt + \sigma dW.$$

- Consider $F(S, t) \equiv Se^{y(T-t)}$.
- Observe that

$$\begin{aligned}\frac{\partial F}{\partial S} &= e^{y(T-t)}, \\ \frac{\partial^2 F}{\partial S^2} &= 0, \\ \frac{\partial F}{\partial t} &= -ySe^{y(T-t)}.\end{aligned}$$

Forward Prices (concluded)

- Then

$$\begin{aligned}dF &= e^{y(T-t)} dS - ySe^{y(T-t)} dt \\&= Se^{y(T-t)} (\mu dt + \sigma dW) - ySe^{y(T-t)} dt \\&= F(\mu - y) dt + F\sigma dW.\end{aligned}$$

- Thus F follows

$$\frac{dF}{F} = (\mu - y) dt + \sigma dW.$$

- This result has applications in forward and futures contracts.^a

^aIt is also consistent with p. 499.

Ornstein-Uhlenbeck Process

- The Ornstein-Uhlenbeck process:

$$dX = -\kappa X dt + \sigma dW,$$

where $\kappa, \sigma \geq 0$.

- It is known that

$$\begin{aligned} E[X(t)] &= e^{-\kappa(t-t_0)} E[x_0], \\ \text{Var}[X(t)] &= \frac{\sigma^2}{2\kappa} \left(1 - e^{-2\kappa(t-t_0)}\right) + e^{-2\kappa(t-t_0)} \text{Var}[x_0], \\ \text{Cov}[X(s), X(t)] &= \frac{\sigma^2}{2\kappa} e^{-\kappa(t-s)} \left[1 - e^{-2\kappa(s-t_0)}\right] \\ &\quad + e^{-\kappa(t+s-2t_0)} \text{Var}[x_0], \end{aligned}$$

for $t_0 \leq s \leq t$ and $X(t_0) = x_0$.

Ornstein-Uhlenbeck Process (continued)

- $X(t)$ is normally distributed if x_0 is a constant or normally distributed.
- X is said to be a normal process.
- $E[x_0] = x_0$ and $\text{Var}[x_0] = 0$ if x_0 is a constant.
- The Ornstein-Uhlenbeck process has the following mean reversion property.
 - When $X > 0$, X is pulled toward zero.
 - When $X < 0$, it is pulled toward zero again.

Ornstein-Uhlenbeck Process (continued)

- A generalized version:

$$dX = \kappa(\mu - X) dt + \sigma dW,$$

where $\kappa, \sigma \geq 0$.

- Given $X(t_0) = x_0$, a constant, it is known that

$$\begin{aligned} E[X(t)] &= \mu + (x_0 - \mu) e^{-\kappa(t-t_0)}, \\ \text{Var}[X(t)] &= \frac{\sigma^2}{2\kappa} \left[1 - e^{-2\kappa(t-t_0)} \right], \end{aligned} \quad (61)$$

for $t_0 \leq t$.

Ornstein-Uhlenbeck Process (concluded)

- The mean and standard deviation are roughly μ and $\sigma/\sqrt{2\kappa}$, respectively.
- For large t , the probability of $X < 0$ is extremely unlikely in any finite time interval when $\mu > 0$ is large relative to $\sigma/\sqrt{2\kappa}$.
- The process is mean-reverting.
 - X tends to move toward μ .
 - Useful for modeling term structure, stock price volatility, and stock price return.

Square-Root Process

- Suppose X is an Ornstein-Uhlenbeck process.
- Ito's lemma says $V \equiv X^2$ has the differential,

$$\begin{aligned}dV &= 2X dX + (dX)^2 \\&= 2\sqrt{V} (-\kappa\sqrt{V} dt + \sigma dW) + \sigma^2 dt \\&= (-2\kappa V + \sigma^2) dt + 2\sigma\sqrt{V} dW,\end{aligned}$$

a square-root process.

Square-Root Process (continued)

- In general, the square-root process has the stochastic differential equation,

$$dX = \kappa(\mu - X) dt + \sigma\sqrt{X} dW,$$

where $\kappa, \sigma \geq 0$ and $X(0)$ is a nonnegative constant.

- Like the Ornstein-Uhlenbeck process, it possesses mean reversion: X tends to move toward μ , but the volatility is proportional to \sqrt{X} instead of a constant.

Square-Root Process (continued)

- When X hits zero and $\mu \geq 0$, the probability is one that it will not move below zero.
 - Zero is a reflecting boundary.
- Hence, the square-root process is a good candidate for modeling interest rates.^a
- The Ornstein-Uhlenbeck process, in contrast, allows negative interest rates.^b
- The two processes are related (see p. 559).

^aCox, Ingersoll, and Ross (1985).

^bBut some rates have gone negative in Europe in 2015!

Square-Root Process (concluded)

- The random variable $2cX(t)$ follows the noncentral chi-square distribution,^a

$$\chi \left(\frac{4\kappa\mu}{\sigma^2}, 2cX(0) e^{-\kappa t} \right),$$

where $c \equiv (2\kappa/\sigma^2)(1 - e^{-\kappa t})^{-1}$.

- Given $X(0) = x_0$, a constant,

$$E[X(t)] = x_0 e^{-\kappa t} + \mu (1 - e^{-\kappa t}),$$

$$\text{Var}[X(t)] = x_0 \frac{\sigma^2}{\kappa} (e^{-\kappa t} - e^{-2\kappa t}) + \mu \frac{\sigma^2}{2\kappa} (1 - e^{-\kappa t})^2,$$

for $t \geq 0$.

^aWilliam Feller (1906–1970) in 1951.

Modeling Stock Prices

- The most popular stochastic model for stock prices has been the geometric Brownian motion,

$$\frac{dS}{S} = \mu dt + \sigma dW.$$

- The continuously compounded rate of return $X \equiv \ln S$ follows

$$dX = (\mu - \sigma^2/2) dt + \sigma dW$$

by Ito's lemma.^a

^aSee also Eq. (59) on p. 547. Consistent with Lemma 10 (p. 278).

Local-Volatility Models

- The more general deterministic volatility model posits

$$\frac{dS}{S} = (r_t - q_t) dt + \sigma(S, t) dW,$$

where instantaneous volatility $\sigma(S, t)$ is called the local volatility function.^a

- A (weak) solution exists if $S\sigma(S, t)$ is continuous and grows at most linearly in S and t .^b

^aDerman and Kani (1994); Dupire (1994).

^bSkorokhod (1961).

Local-Volatility Models (continued)

- Theoretically,^a

$$\sigma(X, T)^2 = 2 \frac{\frac{\partial C}{\partial T} + (r_T - q_T)X \frac{\partial C}{\partial X} + q_T C}{X^2 \frac{\partial^2 C}{\partial X^2}}. \quad (62)$$

- C is the call price at time $t = 0$ (today) with strike price X and time to maturity T .
- $\sigma(X, T)$ is the local volatility that will prevail at *future time* T and *stock price* $S_T = X$.

^aDupire (1994); Andersen and Brotherton-Ratcliffe (1998).

Local-Volatility Models (continued)

- For more general models, this equation gives the expectation as seen from today, under the risk-neutral probability, of the instantaneous variance at time T given that $S_T = X$.^a
- In practice, $\sigma(S, t)^2$ may have spikes, vary wildly, or even be negative.
- The term $\partial^2 C / \partial X^2$ in the denominator often results in numerical instability.
- Now, denote the implied volatility surface by $\Sigma(X, T)$ and the local volatility surface by $\sigma(S, t)$.

^aDerman and Kani (1997).

Local-Volatility Models (continued)

- The relation between $\Sigma(X, T)$ and $\sigma(X, T)$ is^a

$$\sigma(X, T)^2 = \frac{\Sigma^2 + 2\Sigma\tau \left[\frac{\partial \Sigma}{\partial T} + (r_T - q_T)X \frac{\partial \Sigma}{\partial X} \right]}{\left(1 - \frac{Xy}{\Sigma} \frac{\partial \Sigma}{\partial X}\right)^2 + X\Sigma\tau \left[\frac{\partial \Sigma}{\partial X} - \frac{X\Sigma\tau}{4} \left(\frac{\partial \Sigma}{\partial X}\right)^2 + X \frac{\partial^2 \Sigma}{\partial X^2} \right]},$$

$$\tau \equiv T - t,$$

$$y \equiv \ln(X/S_t) + \int_t^T (q_s - r_s) ds.$$

- Although this version may be more stable than Eq. (62) on p. 565, it is expected to suffer from similar problems.

^aAndreasen (1996); Andersen and Brotherton-Ratcliffe (1998); Gatheral (2003); Wilmott (2006); Kamp (2009).

Local-Volatility Models (continued)

- Small changes to the implied volatility surface may produce big changes to the local volatility surface.
- In reality, option prices only exist for a finite set of maturities and strike prices.
- Hence interpolation and extrapolation may be needed to construct the volatility surface.
- But some implied volatility surfaces generate option prices that allow arbitrage profits.

Local-Volatility Models (continued)

- For example, consider the following implied volatility surface:^a

$$\Sigma(X, T)^2 = a_{\text{ATM}}(T) + b(X - S_0)^2, \quad b > 0.$$

- It generates higher prices for out-of-the-money options than in-the-money options for T large enough.^b

^aATM: at-the-money.

^bRebonato (2004).

Local-Volatility Models (continued)

- Let $x \equiv \ln(X/S_0) - rT$.
- For X large enough,^a

$$\Sigma(X, T)^2 < 2 \frac{|x|}{T}.$$

- For X small enough,^b

$$\Sigma(X, T)^2 < \beta \frac{|x|}{T} \quad \text{for any } \beta > 2.$$

^aLee (2004).

^bLee (2004).

Local-Volatility Models (concluded)

- There exist conditions for a set of option prices to be arbitrage-free.^a
- For some vanilla equity options, the Black-Scholes model “seems” better than the local-volatility model.^b

^aDavis and Hobson (2007).

^bDumas, Fleming, and Whaley (1998).

Implied and Local Volatility Surfaces^a

^aContributed by Mr. Lok, U Hou (D99922028) on April 5, 2014.

Implied Trees

- The trees for the local volatility model are called implied trees.^a
- Their construction requires option prices at all strike prices and maturities.
 - That is, an implied volatility surface.
- The local volatility model does *not* require that the implied tree combine.

^aDerman and Kani (1994); Dupire (1994); Rubinstein (1994).

Implied Trees (concluded)

- How to construct an implied tree with efficiency, valid probabilities and stability has been open for a long time.^a
 - Reasons may include: noise and nonsynchrony in data, arbitrage opportunities in the smoothed and interpolated/extrapolated implied volatility surface, wrong model, etc.
- Numerically, inversion is an ill-posed problem.
- It is partially solved recently.^b

^aDerman and Kani (1994); Derman, Kani, and Chriss (1996); Coleman, Kim, Li, and Verma (2000); Ayache, Henrotte, Nassar, and Wang (2004); Kamp (2009).

Continuous-Time Derivatives Pricing

I have hardly met a mathematician
who was capable of reasoning.
— Plato (428 B.C.–347 B.C.)

Fischer [Black] is the only real genius
I've ever met in finance. Other people,
like Robert Merton or Stephen Ross,
are just very smart and quick,
but they think like me.

Fischer came from someplace else entirely.
— John C. Cox, quoted in Mehrling (2005)

Toward the Black-Scholes Differential Equation

- The price of any derivative on a non-dividend-paying stock must satisfy a partial differential equation (PDE).
- The key step is recognizing that the same random process drives both securities.
- As their prices are perfectly correlated, we figure out the amount of stock such that the gain from it offsets exactly the loss from the derivative.
- The removal of uncertainty forces the portfolio's return to be the riskless rate.
- PDEs allow many numerical methods to be applicable.

Assumptions^a

- The stock price follows $dS = \mu S dt + \sigma S dW$.
- There are no dividends.
- Trading is continuous, and short selling is allowed.
- There are no transactions costs or taxes.
- All securities are infinitely divisible.
- The term structure of riskless rates is flat at r .
- There is unlimited riskless borrowing and lending.
- t is the current time, T is the expiration time, and $\tau \equiv T - t$.

^aDerman and Taleb (2005) summarizes criticisms on these assumptions and the replication argument.

Black-Scholes Differential Equation

- Let C be the price of a derivative on S .
- From Ito's lemma (p. 540),

$$dC = \left(\mu S \frac{\partial C}{\partial S} + \frac{\partial C}{\partial t} + \frac{1}{2} \sigma^2 S^2 \frac{\partial^2 C}{\partial S^2} \right) dt + \sigma S \frac{\partial C}{\partial S} dW.$$

- The same W drives both C and S .
- Short one derivative and long $\partial C / \partial S$ shares of stock (call it Π).
- By construction,

$$\Pi = -C + S(\partial C / \partial S).$$

Black-Scholes Differential Equation (continued)

- The change in the value of the portfolio at time dt is^a

$$d\Pi = -dC + \frac{\partial C}{\partial S} dS.$$

- Substitute the formulas for dC and dS into the partial differential equation to yield

$$d\Pi = \left(-\frac{\partial C}{\partial t} - \frac{1}{2} \sigma^2 S^2 \frac{\partial^2 C}{\partial S^2} \right) dt.$$

- As this equation does not involve dW , the portfolio is riskless during dt time: $d\Pi = r\Pi dt$.

^aMathematically speaking, it is not quite right (Bergman, 1982).

Black-Scholes Differential Equation (continued)

- So

$$\left(\frac{\partial C}{\partial t} + \frac{1}{2} \sigma^2 S^2 \frac{\partial^2 C}{\partial S^2} \right) dt = r \left(C - S \frac{\partial C}{\partial S} \right) dt.$$

- Equate the terms to finally obtain

$$\frac{\partial C}{\partial t} + rS \frac{\partial C}{\partial S} + \frac{1}{2} \sigma^2 S^2 \frac{\partial^2 C}{\partial S^2} = rC.$$

- This is a backward equation, which describes the dynamics of a derivative's price *forward* in physical time.

Black-Scholes Differential Equation (concluded)

- When there is a dividend yield q ,

$$\frac{\partial C}{\partial t} + (r - q) S \frac{\partial C}{\partial S} + \frac{1}{2} \sigma^2 S^2 \frac{\partial^2 C}{\partial S^2} = rC. \quad (63)$$

- The local-volatility model (62) on p. 565 is simply the dual of this equation:^a

$$\frac{\partial C}{\partial T} + (r_T - q_T) X \frac{\partial C}{\partial X} - \frac{1}{2} \sigma(X, T)^2 X^2 \frac{\partial^2 C}{\partial X^2} = -q_T C.$$

- This is a forward equation, which describes the dynamics of a derivative's price *backward* in maturity time.

^aDerman and Kani (1997).

Rephrase

- The Black-Scholes differential equation can be expressed in terms of sensitivity numbers,

$$\Theta + rS\Delta + \frac{1}{2}\sigma^2 S^2\Gamma = rC. \quad (64)$$

- Identity (64) leads to an alternative way of computing Θ numerically from Δ and Γ .
- When a portfolio is delta-neutral,

$$\Theta + \frac{1}{2}\sigma^2 S^2\Gamma = rC.$$

- A definite relation thus exists between Γ and Θ .

Black-Scholes Differential Equation: An Alternative

- Perform the change of variable $V \equiv \ln S$.
- The option value becomes $U(V, t) \equiv C(e^V, t)$.
- Furthermore,

$$\begin{aligned}\frac{\partial C}{\partial t} &= \frac{\partial U}{\partial t}, \\ \frac{\partial C}{\partial S} &= \frac{1}{S} \frac{\partial U}{\partial V}, \\ \frac{\partial^2 C}{\partial^2 S} &= \frac{1}{S^2} \frac{\partial^2 U}{\partial V^2} - \frac{1}{S^2} \frac{\partial U}{\partial V}.\end{aligned}\tag{65}$$

- Equation (65) is an alternative way to calculate gamma.

Black-Scholes Differential Equation: An Alternative (concluded)

- The Black-Scholes differential equation (63) becomes

$$\frac{1}{2} \sigma^2 \frac{\partial^2 U}{\partial V^2} + \left(r - q - \frac{\sigma^2}{2} \right) \frac{\partial U}{\partial V} - rU + \frac{\partial U}{\partial t} = 0$$

subject to $U(V, T)$ being the payoff such as $\max(X - e^V, 0)$.

[Black] got the equation [in 1969] but then
was unable to solve it. Had he been a better
physicist he would have recognized it as a form
of the familiar heat exchange equation,
and applied the known solution. Had he been
a better mathematician, he could have
solved the equation from first principles.
Certainly Merton would have known exactly
what to do with the equation
had he ever seen it.
— Perry Mehrling (2005)

PDEs for Asian Options

- Add the new variable $A(t) \equiv \int_0^t S(u) du$.
- Then the value V of the Asian option satisfies this two-dimensional PDE:^a

$$\frac{\partial V}{\partial t} + rS \frac{\partial V}{\partial S} + \frac{1}{2} \sigma^2 S^2 \frac{\partial^2 V}{\partial S^2} + S \frac{\partial V}{\partial A} = rV.$$

- The terminal conditions are

$$V(T, S, A) = \max \left(\frac{A}{T} - X, 0 \right) \quad \text{for call,}$$

$$V(T, S, A) = \max \left(X - \frac{A}{T}, 0 \right) \quad \text{for put.}$$

^aKemna and Vorst (1990).

PDEs for Asian Options (continued)

- The two-dimensional PDE produces algorithms similar to that on pp. 385ff.
- But one-dimensional PDEs are available for Asian options.^a
- For example, Večer (2001) derives the following PDE for Asian calls:

$$\frac{\partial u}{\partial t} + r \left(1 - \frac{t}{T} - z \right) \frac{\partial u}{\partial z} + \frac{\left(1 - \frac{t}{T} - z \right)^2 \sigma^2}{2} \frac{\partial^2 u}{\partial z^2} = 0$$

with the terminal condition $u(T, z) = \max(z, 0)$.

^aRogers and Shi (1995); Večer (2001); Dubois and Lelièvre (2005).

PDEs for Asian Options (concluded)

- For Asian puts:

$$\frac{\partial u}{\partial t} + r \left(\frac{t}{T} - 1 - z \right) \frac{\partial u}{\partial z} + \frac{\left(\frac{t}{T} - 1 - z \right)^2 \sigma^2}{2} \frac{\partial^2 u}{\partial z^2} = 0$$

with the same terminal condition.

- One-dimensional PDEs lead to highly efficient numerical methods.

The Hull-White Model

- Hull and White (1987) postulate the following model,

$$\begin{aligned}\frac{dS}{S} &= r dt + \sqrt{V} dW_1, \\ dV &= \mu_v V dt + bV dW_2.\end{aligned}$$

- Above, V is the instantaneous variance.
- They assume μ_v depends on V and t (but not S).

The SABR Model

- Hagan, Kumar, Lesniewski, and Woodward (2002) postulate the following model,

$$\begin{aligned}\frac{dS}{S} &= r dt + S^\theta V dW_1, \\ dV &= bV dW_2,\end{aligned}$$

for $0 \leq \theta \leq 1$.

- A nice feature of this model is that the implied volatility surface has a compact approximate closed form.

The Hilliard-Schwartz Model

- Hilliard and Schwartz (1996) postulate the following general model,

$$\begin{aligned}\frac{dS}{S} &= r dt + f(S)V^a dW_1, \\ dV &= \mu(V) dt + bV dW_2,\end{aligned}$$

for some well-behaved function $f(S)$ and constant a .

The Blacher Model

- Blacher (2002) postulates the following model,

$$\begin{aligned}\frac{dS}{S} &= r dt + \sigma \left[1 + \alpha(S - S_0) + \beta(S - S_0)^2 \right] dW_1, \\ d\sigma &= \kappa(\theta - \sigma) dt + \epsilon\sigma dW_2.\end{aligned}$$

- So the volatility σ follows a mean-reverting process to level θ .

Heston's Stochastic-Volatility Model

- Heston (1993) assumes the stock price follows

$$\frac{dS}{S} = (\mu - q) dt + \sqrt{V} dW_1, \quad (66)$$

$$dV = \kappa(\theta - V) dt + \sigma\sqrt{V} dW_2. \quad (67)$$

- V is the instantaneous variance, which follows a square-root process.
 - dW_1 and dW_2 have correlation ρ .
 - The riskless rate r is constant.
- It may be the most popular continuous-time stochastic-volatility model.^a

^aChristoffersen, Heston, and Jacobs (2009).

Heston's Stochastic-Volatility Model (continued)

- Heston assumes the market price of risk is $b_2\sqrt{V}$.
- So $\mu = r + b_2V$.
- Define

$$\begin{aligned}dW_1^* &= dW_1 + b_2\sqrt{V} dt, \\dW_2^* &= dW_2 + \rho b_2\sqrt{V} dt, \\ \kappa^* &= \kappa + \rho b_2\sigma, \\ \theta^* &= \frac{\theta\kappa}{\kappa + \rho b_2\sigma}.\end{aligned}$$

- dW_1^* and dW_2^* have correlation ρ .

Heston's Stochastic-Volatility Model (continued)

- Under the risk-neutral probability measure Q , both W_1^* and W_2^* are Wiener processes.
- Heston's model becomes, under probability measure Q ,

$$\begin{aligned}\frac{dS}{S} &= (r - q) dt + \sqrt{V} dW_1^*, \\ dV &= \kappa^* (\theta^* - V) dt + \sigma \sqrt{V} dW_2^*.\end{aligned}$$

Heston's Stochastic-Volatility Model (continued)

- Define

$$\begin{aligned}\phi(u, \tau) = & \exp \left\{ \imath u (\ln S + (r - q) \tau) \right. \\ & + \theta^* \kappa^* \sigma^{-2} \left[(\kappa^* - \rho \sigma \imath u - d) \tau - 2 \ln \frac{1 - g e^{-d\tau}}{1 - g} \right] \\ & \left. + \frac{v \sigma^{-2} (\kappa^* - \rho \sigma \imath u - d) (1 - e^{-d\tau})}{1 - g e^{-d\tau}} \right\},\end{aligned}$$

$$d = \sqrt{(\rho \sigma \imath u - \kappa^*)^2 - \sigma^2 (-\imath u - u^2)},$$

$$g = (\kappa^* - \rho \sigma \imath u - d) / (\kappa^* - \rho \sigma \imath u + d).$$

Heston's Stochastic-Volatility Model (concluded)

The formulas are^a

$$\begin{aligned}
 C &= S \left[\frac{1}{2} + \frac{1}{\pi} \int_0^\infty \operatorname{Re} \left(\frac{X^{-\imath u} \phi(u - \imath, \tau)}{\imath u S e^{r\tau}} \right) du \right] \\
 &\quad - X e^{-r\tau} \left[\frac{1}{2} + \frac{1}{\pi} \int_0^\infty \operatorname{Re} \left(\frac{X^{-\imath u} \phi(u, \tau)}{\imath u} \right) du \right], \\
 P &= X e^{-r\tau} \left[\frac{1}{2} - \frac{1}{\pi} \int_0^\infty \operatorname{Re} \left(\frac{X^{-\imath u} \phi(u, \tau)}{\imath u} \right) du \right], \\
 &\quad - S \left[\frac{1}{2} - \frac{1}{\pi} \int_0^\infty \operatorname{Re} \left(\frac{X^{-\imath u} \phi(u - \imath, \tau)}{\imath u S e^{r\tau}} \right) du \right],
 \end{aligned}$$

where $\imath = \sqrt{-1}$ and $\operatorname{Re}(x)$ denotes the real part of the complex number x .

Stochastic-Volatility Models and Further Extensions^a

- How to explain the October 1987 crash?
- Stochastic-volatility models require an implausibly high-volatility level prior to *and* after the crash.
- Merton (1976) proposed jump models.
- Discontinuous jump models *in the asset price* can alleviate the problem somewhat.

^aEraker (2004).

Stochastic-Volatility Models and Further Extensions (continued)

- But if the jump intensity is a constant, it cannot explain the tendency of large movements to cluster over time.
- This assumption also has no impacts on option prices.
- Jump-diffusion models combine both.
 - E.g., add a jump process to Eq. (66) on p. 594.
 - Closed-form formulas exist for GARCH-jump option pricing models.^a

^aLiou (R92723060) (2005).

Stochastic-Volatility Models and Further Extensions (concluded)

- But they still do not adequately describe the systematic variations in option prices.^a
- Jumps *in volatility* are alternatives.^b
 - E.g., add correlated jump processes to Eqs. (66) and Eq. (67) on p. 594.
- Such models allow high level of volatility caused by a jump to volatility.^c

^aBates (2000) and Pan (2002).

^bDuffie, Pan, and Singleton (2000).

^cEraker, Johnnes, and Polson (2000).

Complexities of Stochastic-Volatility Models

- A few stochastic-volatility models suffer from subexponential ($c^{\sqrt{n}}$) tree size.
- Examples include the Hull-White (1987), Hilliard-Schwartz (1996), and SABR (2002) models.^a
- Future research may extend this negative result to more stochastic-volatility models.
 - We suspect many GARCH option pricing models entertain similar problems.^b

Hedging

When Professors Scholes and Merton and I
invested in warrants,
Professor Merton lost the most money.
And I lost the least.
— Fischer Black (1938–1995)

Delta Hedge

- The delta (hedge ratio) of a derivative f is defined as

$$\Delta \equiv \frac{\partial f}{\partial S}.$$

- Thus

$$\Delta f \approx \Delta \times \Delta S$$

for relatively small changes in the stock price, ΔS .

- A delta-neutral portfolio is hedged as it is immunized against small changes in the stock price.
- A trading strategy that dynamically maintains a delta-neutral portfolio is called delta hedge.

Delta Hedge (concluded)

- Delta changes with the stock price.
- A delta hedge needs to be rebalanced periodically in order to maintain delta neutrality.
- In the limit where the portfolio is adjusted continuously, “perfect” hedge is achieved and the strategy becomes self-financing.

Implementing Delta Hedge

- We want to hedge N *short* derivatives.
- Assume the stock pays no dividends.
- The delta-neutral portfolio maintains $N \times \Delta$ shares of stock plus B borrowed dollars such that

$$-N \times f + N \times \Delta \times S - B = 0.$$

- At next rebalancing point when the delta is Δ' , buy $N \times (\Delta' - \Delta)$ shares to maintain $N \times \Delta'$ shares with a total borrowing of $B' = N \times \Delta' \times S' - N \times f'$.
- Delta hedge is the discrete-time analog of the continuous-time limit and will rarely be self-financing.

Example

- A hedger is *short* 10,000 European calls.
- $S = 50$, $\sigma = 30\%$, and $r = 6\%$.
- This call's expiration is four weeks away, its strike price is \$50, and each call has a current value of $f = 1.76791$.
- As an option covers 100 shares of stock, $N = 1,000,000$.
- The trader adjusts the portfolio weekly.
- The calls are replicated well if the cumulative cost of trading *stock* is close to the call premium's FV.^a

^aThis example takes the replication viewpoint.

Example (continued)

- As $\Delta = 0.538560$

$$N \times \Delta = 538,560$$

shares are purchased for a total cost of

$$538,560 \times 50 = 26,928,000$$

dollars to make the portfolio delta-neutral.

- The trader finances the purchase by borrowing

$$B = N \times \Delta \times S - N \times f = 25,160,090$$

dollars net.^a

^aThis takes the hedging viewpoint — an alternative. See an exercise in the text.

Example (continued)

- At 3 weeks to expiration, the stock price rises to \$51.
- The new call value is $f' = 2.10580$.
- So the portfolio is worth

$$-N \times f' + 538,560 \times 51 - Be^{0.06/52} = 171,622$$

before rebalancing.

Example (continued)

- A delta hedge does not replicate the calls perfectly; it is not self-financing as \$171,622 can be withdrawn.
- The magnitude of the tracking error—the variation in the net portfolio value—can be mitigated if adjustments are made more frequently.
- In fact, the tracking error over *one* rebalancing act is positive about 68% of the time, but its expected value is essentially zero.^a
- The tracking error at maturity is proportional to vega.^b

^aBoyle and Emanuel (1980).

^bKamal and Derman (1999).

Example (continued)

- In practice tracking errors will cease to decrease beyond a certain rebalancing frequency.

- With a higher delta $\Delta' = 0.640355$, the trader buys

$$N \times (\Delta' - \Delta) = 101,795$$

shares for \$5,191,545.

- The number of shares is increased to $N \times \Delta' = 640,355$.

Example (continued)

- The cumulative cost is

$$26,928,000 \times e^{0.06/52} + 5,191,545 = 32,150,634.$$

- The portfolio is again delta-neutral.

τ	S	Option value f	Delta Δ	Change in delta	No. shares bought $N \times (5)$	Cost of shares $(1) \times (6)$	Cumulative cost $FV(8') + (7)$
	(1)	(2)	(3)	(5)	(6)	(7)	(8)
4	50	1.7679	0.53856	—	538,560	26,928,000	26,928,000
3	51	2.1058	0.64036	0.10180	101,795	5,191,545	32,150,634
2	53	3.3509	0.85578	0.21542	215,425	11,417,525	43,605,277
1	52	2.2427	0.83983	-0.01595	-15,955	-829,660	42,825,960
0	54	4.0000	1.00000	0.16017	160,175	8,649,450	51,524,853

The total number of shares is 1,000,000 at expiration (trading takes place at expiration, too).

Example (concluded)

- At expiration, the trader has 1,000,000 shares.
- They are exercised against by the in-the-money calls for \$50,000,000.
- The trader is left with an obligation of

$$51,524,853 - 50,000,000 = 1,524,853,$$

which represents the replication cost.

- Compared with the FV of the call premium,

$$1,767,910 \times e^{0.06 \times 4/52} = 1,776,088,$$

the net gain is $1,776,088 - 1,524,853 = 251,235$.
