

Algorithm Design and Analysis Introduction

http://ada.miulab.tw slido: #ADA2020

Yun-Nung (Vivian) Chen

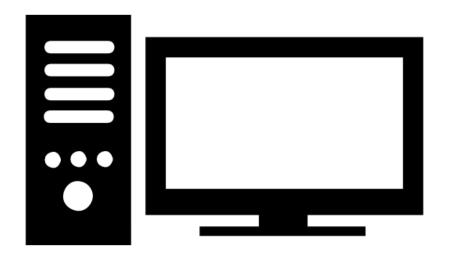

Outline

- Terminology
 - Problem (問題)
 - Problem instance (個例)
 - Computation model (計算模型)
 - Algorithm (演算法)
 - The hardness of a problem (難度)
- Algorithm Design & Analysis Process
- Review: Asymptotic Analysis
- Algorithm Complexity
- Problem Complexity

Efficiency Measurement = Speed

- Why we care?
 - Computers may be fast, but they are not infinitely fast
 - Memory may be inexpensive, but it is not free

Terminology

Textbook Ch. 1 – The Role of Algorithms in Computing

Problem (問題)

The champion problem

- Input: n distinct integers $A[1], A[2], \ldots, A[n]$.
- Output: the index i with $1 \le i \le n$ such that

$$A[i] = \max_{1 \le j \le n} A[j].$$

Problem Instance (個例)

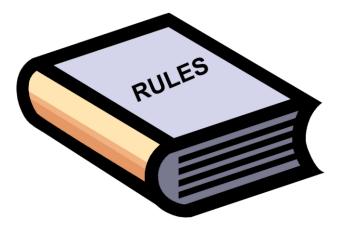

• An instance of the champion problem

5 distinct integers 7, 4, 2, 9, 8.

Computation Model (計算模型)

- Each problem must have its rule (遊戲規則)
- Computation model (計算模型) = rule (遊戲規則)
- The problems with different rules have different hardness levels

Hardness (難易程度)

- How difficult to solve a problem
 - Example: how hard is the champion problem?
 - Following the comparison-based rule

What does "solve (解)" mean?

What does "difficult (難)" mean?

Problem Solving (解題)

- Definition of "solving" a problem
 - Giving an algorithm (演算法) that produces a correct output for any instance of the problem.

Algorithm (演算法)

- Algorithm: a detailed step-by-step instruction
 - Must follow the game rules
 - Like a step-by-step recipe
 - Programming language doesn't matter
 - \rightarrow problem-solving recipe (technology)
- If an algorithm produces a correct output for <u>any instance</u> of the problem
 - \rightarrow this algorithm "solves" the problem

- Hardness of the problem
 - How much effort the best algorithm needs to solve any problem instance
- 防禦力
 - 看看最厲害的賽亞人要花多少攻擊力才能打贏對手

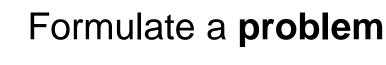

Algorithm Design & Analysis Process

Algorithm Design & Analysis Process

Develop an algorithm

Design Step

Prove the correctness

4

3

Analyze running time/space requirement

Analysis Step

1. Problem Formulation

The champion problem

- Input: n distinct integers $A[1], A[2], \ldots, A[n]$.
- Output: the index i with $1 \le i \le n$ such that

$$A[i] = \max_{1 \le j \le n} A[j].$$

2. Algorithm Design

- Create a detailed recipe for solving the problem
 - Follow the comparison-based rule
 - 不准偷看信封的內容
 - 請別人幫忙「比大小」
- Algorithm: 擂台法
 - 1. int *i, j*;
 - 2. *j* = 1;
 - 3. for $(i = 2; i \le n; i++)$
 - 4. if (A[i] > A[j])
 - **5**. j = i;
 - 6. return *j*;

Q1: Is this a comparison-based algorithm?

Q2: Does it solve the champion

3. Correctness of the Algorithm

• Prove by contradiction (反證法)

The algorithm solves the champion problem.

Proof Let j^* be the correct answer. That is, $A[j^*] = \max\{A[1], \dots, A[n]\}.$

- If $j^* = 1$, then Step 5 is never reached. Therefore, 1 is correctly returned.
- If j* > 1, then in the iteration of the for-loop with i = j*, j becomes j*. By definition of j*, A[j*] > A[i] holds for each i = j* + 1,...,n. Therefore, in the remaining iterations of the for-loop, the value of j does not change. Hence, at the end of the algorithm, j* is correctly returned.

1. int <i>i</i> , <i>j</i> ;	
------------------------------	--

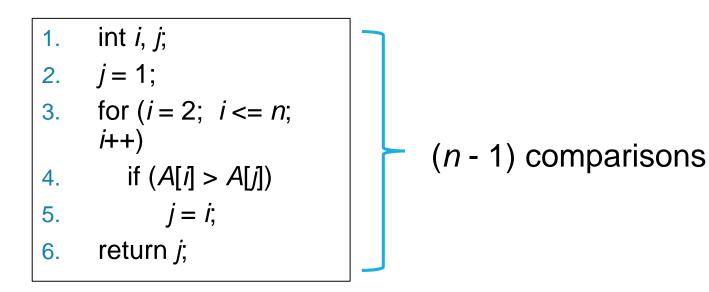

3. for
$$(i = 2; i \le n; i + +)$$

4. if
$$(A[i] > A[j])$$

5.
$$j = i;$$

6. return *j*;

- How much effort the best algorithm needs to solve any problem instance
 - Follow the comparison-based rule
 - 不准偷看信封的内容
 - 請別人幫忙「比大小」
- Effort: we first use the times of comparison for measurement

- The hardness of the champion problem is (*n* 1) comparisons
 - a) There is an algorithm that can solve the problem using at most (n 1) comparisons
 - This can be proved by 擂臺法, which uses (*n*−1) comparisons for any problem instance

b) For any algorithm, there exists a problem instance that requires (n - 1) comparisons

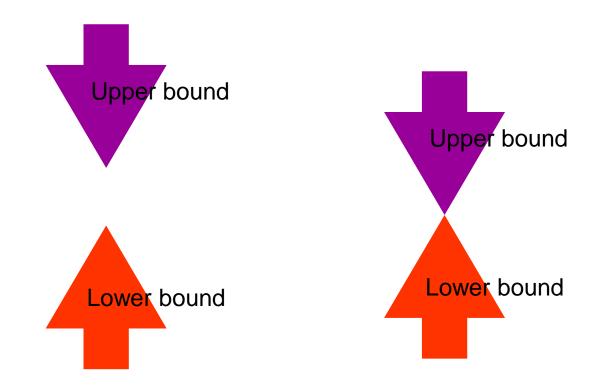

• Why?

- Q: Is there an algorithm that only needs n 2 comparisons?
- A: Impossible!
- Reason
 - A single comparison only decides a loser
 - If there are only n-2 comparisons, the most number of losers is n-2
 - There exists a least 2 integers that did not lose
 - \rightarrow any algorithm cannot tell who the champion is

Finding Hardness

- Use the upper bound and the lower bound
- When they meet each other, we know the hardness of the problem

- Upper bound
 - how many comparisons are <u>sufficient</u> to solve the champion problem
 - Each algorithm provides an upper bound
 - The smarter algorithm provides tighter, lower, and better upper bound

 \rightarrow (2*n* - 2) comparisons

- Lower bound
 - how many comparisons in the worst case are necessary to solve the champion problem
 - Some arguments provide different lower bounds
 - Higher lower bound is better

Every integer needs to be in the comparison once \rightarrow (*n*/2) comparisons

多此一舉擂臺法

1. int *i, j*;

2. j = 1;

- 3. for $(i = 2; i \le n; i++)$
- 4. if ((A[i] > A[j]) && (A[j] < A[i]))
- 5. j = i;6. return *j*;

When upper bound = lower bound, the problem is solved. \rightarrow We figure out the hardness of the problem

4. Algorithm Analysis

- The majority of researchers in algorithms studies the <u>time</u> and <u>space</u> required for solving problems in two directions
 - Upper bounds: designing and analyzing algorithms
 - Lower bounds: providing arguments
- When the upper and lower bounds match, we have an optimal algorithm and the problem is completely resolved

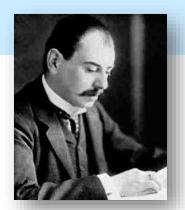

教過

我早就會了!

Donald E. Knuth (1938-)

Motivation

- The hardness of the champion problem is exactly n-1 comparisons
- Different problems may have different 「難度量尺」
 - cannot be interchangeable
- Focus on the standard growth of the function to ignore the <u>unit</u> and <u>coefficient</u> effects

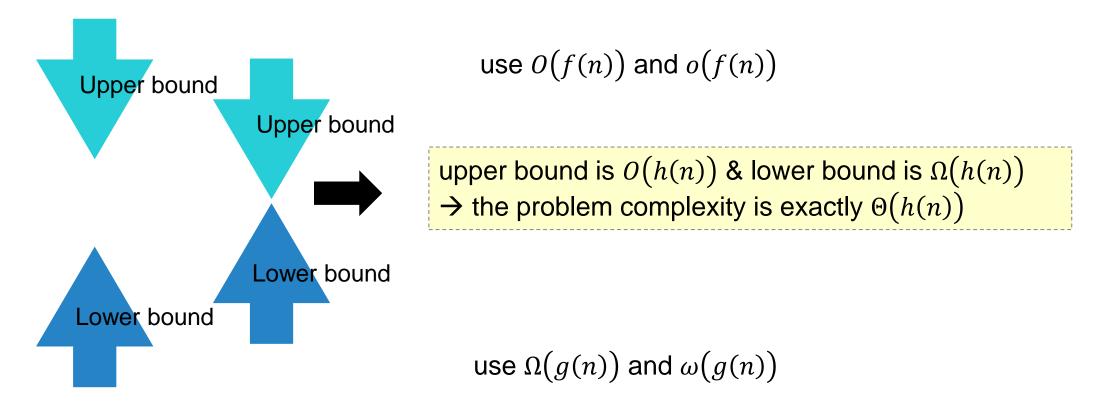

Goal: Finding Hardness

- For a problem *P*, we want to figure out
 - The hardness (complexity) of this problem P is $\Theta(f(n))$
 - *n* is the instance size of this problem *P*
 - f(n) is a function
 - $\Theta(f(n))$ means that "it exactly equals to the growth of the function"
- Then we can argue that under the comparison-based computation model
 - The hardness of the champion problem is $\Theta(n)$
 - The hardness of the sorting problem is $\Theta(n \log n)$

Goal: Finding Hardness

- Use the upper bound and the lower bound
- When they match, we know the hardness of the problem

Goal: Finding Hardness

- First learn how to analyze / measure the effort an algorithm needs
 - Time complexity
 - Space complexity
- Focus on worst-case complexity
 - "average-case" analysis requires the assumption about the probability distribution of problem instances

Types	Description
Worst Case	Maximum running time for any instance of size <i>n</i>
Average Case	Expected running time for a random instance of size n
Amortized	Worse-case running time for a series of operations

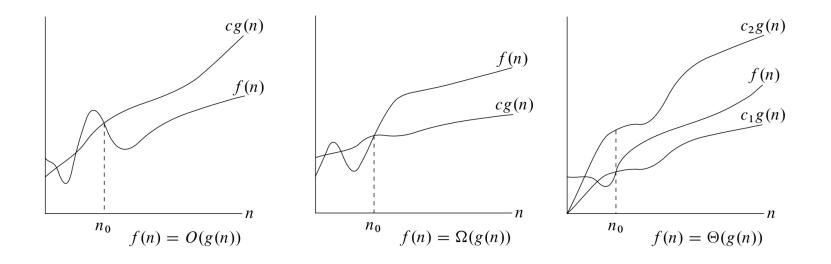

Review of Asymptotic Notation (Textbook Ch. 3.1)

- f(n) = time or space of an algorithm for an input of size n
- Asymptotic analysis: focus on the **growth** of f(n) as $n \to \infty$

Review of Asymptotic Notation (Textbook Ch. 3.1)

- f(n) = time or space of an algorithm for an input of size n
- Asymptotic analysis: focus on the **growth** of f(n) as $n \to \infty$
- O, or Big-Oh: upper bounding function
- Ω , or Big-Omega: **lower** bounding function
- Θ, or Big-Theta: **tightly** bounding function

Formal Definition of Big-Oh (Textbook Ch. 3.1)

• For any two functions f(n) and g(n),

$$f(n) = O(g(n))$$

if there exist positive constants n_0 and c s.t.

$$0 \le f(n) \le c \cdot g(n)$$

for all $n \ge n_0$.

g(n)的某個常數倍 $c \cdot g(n)$ 可以在n夠大時壓得住f(n)

f(n) = O(g(n))

- Intuitive interpretation
 - f(n) does not grow faster than g(n)
- Comments
 - 1) f(n) = O(g(n)) roughly means $f(n) \le g(n)$ in terms of rate of growth
 - 2) "=" is not "equality", it is like " ϵ (belong to)" The equality is $\{f(n)\} \subseteq O(g(n))$
 - 3) We do not write O(g(n)) = f(n)
- Note
 - f(n) and g(n) can be negative for some integers n
 - In order to compare using asymptotic notation O, both have to be <u>non-negative</u> for sufficiently large n
 - This requirement holds for other notations, i.e. Ω , Θ , o, ω

Review of Asymptotic Notation (Textbook Ch. 3.1)

• Benefit

- Ignore the low-order terms, units, and coefficients
- Simplify the analysis
- Example: $f(n) = 5n^3 + 7n^2 8$
 - Upper bound: $f(n) = O(n^3)$, $f(n) = O(n^4)$, $f(n) = O(n^3 \log_2 n)$
 - Lower bound: $f(n) = \Omega(n^3)$, $f(n) = \Omega(n^2)$, $f(n) = \Omega(n\log_2 n)$
 - Tight bound: f(n) = Θ(n³)
 "=" doesn't mean "equal to"
- Q: $f(n) = O(n^3)$ and $f(n) = O(n^4)$, so $O(n^3) = O(n^4)$?
 - $O(n^3)$ represents **a set of functions** that are upper bounded by cn^3 for some constant c when n is large enough
 - In asymptotic analysis, "=" means "ε (belong to)"

Exercise:
$$100n^2 = O(n^3 - n^2)$$
?

• Draft.

$$100n^{2} \leq 100(n^{3} - n^{2})$$
$$\leftarrow 200n^{2} \leq 100n^{3}$$
$$\leftarrow 2 \leq n$$

• Let
$$n_0 = 2$$
 and $c = 100$

$$100n^2 \le 100(n^3 - n^2)$$

holds for $n \ge 2$

$$100n^2 = O(n^3 - n^2)$$

Exercise: $n^2 = O(n)$?

• Disproof.

• Assume for a contradiction that there exist positive constants c and n_0 s.t.

$$n^2 \le cn$$

holds for any integer n with $n \ge n_0$.

• Assume $n = 1 + \lceil \max(n_0, c) \rceil$

and because $\ n>n_0, n>c$, it follows that $n^2>cn$

• Due to contradiction, we know that

$$n^2 \neq O(n)$$

Rules (Textbook Ch. 3.1)

The following statements hold for any real-valued functions f(n)and g(n), where there is a constant n_0 such that f(n) and g(n)are nonnegative for any integer $n \ge n_0$.

- Rule 1: f(n) = O(f(n)).
- Rule 2: If c is a positive constant, then $c \cdot O(f(n)) = O(f(n))$.
- Rule 3: If f(n) = O(g(n)), then O(f(n)) = O(g(n)).
- Rule 4: $O(f(n)) \cdot O(g(n)) = O(f(n) \cdot g(n)).$
- Rule 5: $O(f(n) \cdot g(n)) = f(n) \cdot O(g(n))$.

Other Notations (Textbook Ch. 3.1)

$$\begin{split} f(n) &= O(g(n)) \to f(n) \leq g(n) \text{ in rate of growth} \\ f(n) &= \Omega(g(n)) \to f(n) \geq g(n) \text{ in rate of growth} \\ f(n) &= \Theta(g(n)) \to f(n) = g(n) \text{ in rate of growth} \\ f(n) &= o(g(n)) \to f(n) < g(n) \text{ in rate of growth} \\ f(n) &= \omega(g(n)) \to f(n) > g(n) \text{ in rate of growth} \end{split}$$

Goal: Finding Hardness

- First learn how to analyze / measure the effort an algorithm needs
 - Time complexity
 - Space complexity
- Focus on worst-case complexity
 - "average-case" analysis requires the assumption about the probability distribution of problem instances

Using *O* to give upper bounds on the worst-case time complexity of algorithms

Algorithm Analysis

=O(n)

• 擂台法

1.	int <i>i, j</i> ;		0(1) time
2.	j = 1;		0(1) time
3.	for $(i = 2; i \le n;$	<i>i</i> ++)	O(n) iterations
4.	if $(A[i] > A[j])$		0(1) time
5.	j = i;		0(1) time
6.	return <i>j</i> ;		0(1) time

Adding everything together \rightarrow an upper bound on the worst-case time complexity

- The worst-case time complexity is $O(1) + O(1) + O(n) \cdot (O(1) + O(1)) + O(1)$

 $\begin{array}{ll} 3 \cdot O(1) + O(n) \cdot (2O(1)) \\ = O(1) + O(n) \cdot O(1) & \text{Rule 2} \\ = O(1) + O(n) & \text{Rule 4} \\ = O(n) + O(n) & 1 = O(n) \& \text{Rule 3} \\ = 2 \cdot O(n) & \text{Rule 2} \end{array}$

Sorting Problem

slido event code: #ADA2020

• Input:

An array A of n distinct integers.

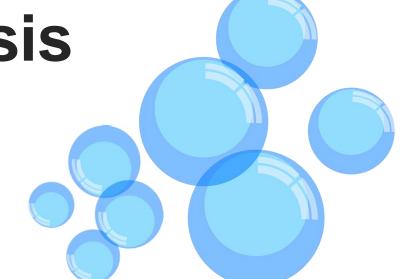

• Output:

Reorder A such that $A[1] < A[2] < \cdots < A[n]$.

Algorithm Analysis

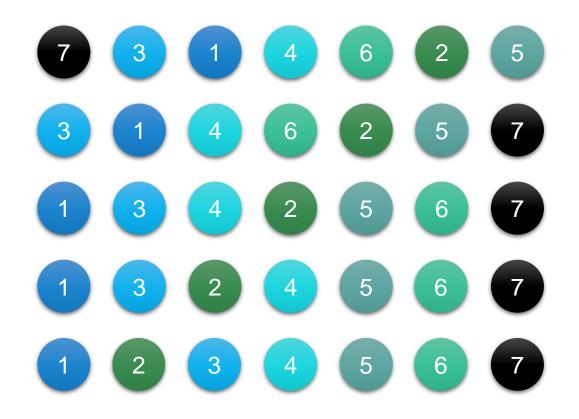

• Bubble-Sort Algorithm

1.	int <i>i</i> , <i>done</i> ;	O(1) time
2.	do {	f(n) iterations
3.	<i>done</i> = 1;	O(1) time
4.	for (<i>i</i> = 1; <i>i</i> < <i>n</i> ; <i>i</i> ++) {	O(n) iterations
5.	if (<i>A</i> [<i>i</i>] > <i>A</i> [<i>i</i> + 1]) {	O(1) time
6.	exchange <i>A</i> [<i>i</i>] and <i>A</i> [<i>i</i> + 1];	O(1) time
7.	done = 0;	O(1) time
8.	}	
9.	}	
10.	} while (<i>done</i> == 0)	

```
O(1) + f(n) \cdot (O(1) + O(n) \cdot O(1))
= O(1) + f(n) \cdot O(n)
= f(n) \cdot O(n)
= O(n^2)
f(n) = O(n)
prove by induction
```

Example Illustration

Goal: Finding Hardness

- First learn how to analyze / measure the effort an algorithm needs
 - Time complexity
 - Space complexity
- Focus on worst-case complexity
 - "average-case" analysis requires the assumption about the probability distribution of problem instances

Using *O* to give **upper bounds** on the worst-case time complexity of algorithms

Using Ω to give **lower bounds** on the worst-case time complexity of algorithms

Algorithm Analysis

• 擂台法

1.	int <i>i</i> ;	$\Omega(1)$ time
2.	int <i>m</i> = <i>A</i> [1];	$\Omega(1)$ time
3.	for (<i>i</i> = 2; <i>i</i> <= <i>n</i> ; <i>i</i> ++) {	$\Omega(n)$ iterations
4.	if (<i>A</i> [<i>i</i>] > <i>m</i>)	$\Omega(1)$ time
5.	m = A[i];	$\Omega(1)$ time
6.	}	
7.	return <i>m</i> ;	$\Omega(1)$ time

 $\begin{aligned} 3 \cdot \Omega(1) + \Omega(n) \cdot (2 \cdot \Omega(1)) \\ = \Omega(1) + \Omega(n) \cdot \Omega(1) \\ = \Omega(1) + \Omega(n) \\ = \Omega(n) \end{aligned}$

Adding everything together→ a lower bound on the worst-case time complexity?

Algorithm Analysis

• 百般無聊擂台法

1. int <i>i</i> ; $\Omega(1)$ til	
	me
2. int $m = A[1];$ $\Omega(1)$ til	me
3. for $(i = 2; i \le n; i + +)$ { $\Omega(n)$ ite	erations
4. if $(A[i] > m)$ $\Omega(1)$ til	me
5. $m = A[i];$ $\Omega(1)$ tin	me
6. if $(i == n)$ $\Omega(1)$ the set of the set	me
7. do <i>i</i> ++ <i>n</i> times $\Omega(n)$ times	me
8. }	
9. return m ; $\Omega(1)$ til	me

 $\begin{aligned} 3 \cdot \Omega(1) &+ \Omega(n) \cdot (3 \cdot \Omega(1) + \Omega(n)) \\ &= \Omega(1) + \Omega(n) \cdot \Omega(n) \\ &= \Omega(1) + \Omega(n^2) \\ &= \Omega(n^2) \end{aligned}$

Adding together may result in errors. The safe way is to analyze using **problem instances**.

e.g. try A[i] = i or A[i]=2(n-i) to check the time complexity $\rightarrow \Omega(1)$

Algorithm Analysis

Bubble-Sort Algorithm

int *i*, *done*; 1.

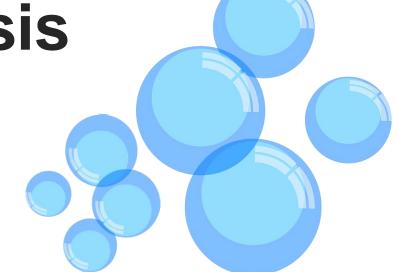

- 2. do { f(n) iterations
- done = 1; 3.

8.

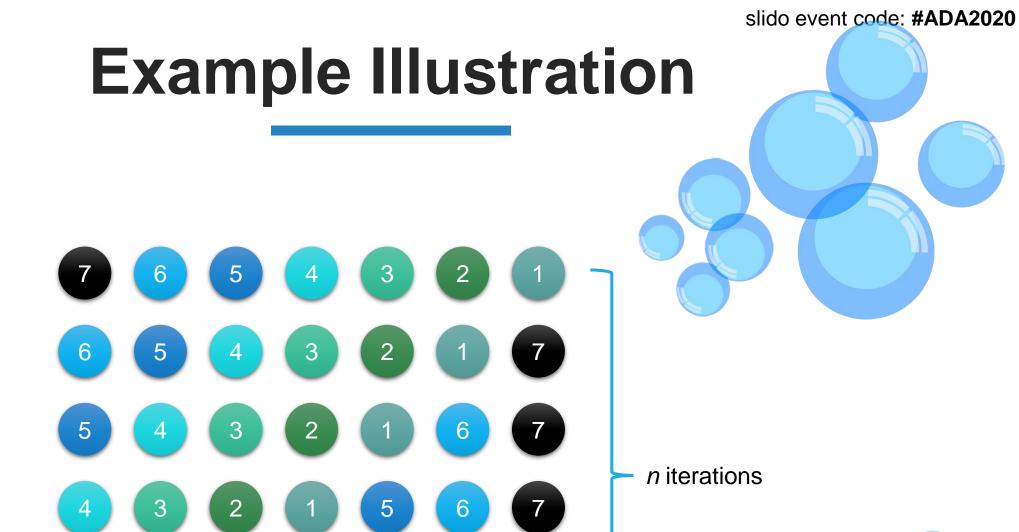

9.

- for $(i = 1; i < n; i + +) \{ \Omega(n) \text{ time } \}$ 4.
- if (A[i] > A[i + 1]) { 5.
- exchange A[i] and A[i + 1]; 6. 7.
 - done = 0;

} while (*done* == 0) 10.

When A is decreasing, $f(n) = \Omega(n)$. Therefore, the worst-case time complexity of Bubble-Sort is $f(n) \cdot \Omega(n) = \Omega(n^2)$

<u>Algorithm</u> Complexity

In the worst case, what is the growth of function an algorithm takes

Time Complexity of an Algorithm

- We say that the (worst-case) time complexity of Algorithm A is $\Theta(f(n))$ if
- 1. Algorithm A runs in time O(f(n)) &
- 2. Algorithm A runs in time $\Omega(f(n))$ (in the worst case) \circ An input instance I(n) s.t. Algorithm A runs in $\Omega(f(n))$ for each n

Tightness of the Complexity

- If we say that the time complexity analysis about O(f(n)) is tight
- = the algorithm runs in time $\Omega(f(n))$ in the worst case
- = (worst-case) time complexity of the algorithm is $\Theta(f(n))$
 - Not over-estimate the worst-case time complexity of the algorithm
- If we say that the time complexity analysis of Bubble-Sort algorithm about $O\left(n^2
 ight)$ is tight
- = Time complexity of Bubble-Sort algorithm is $\Omega(n^2)$
- = Time complexity of Bubble-Sort algorithm is $\Theta(n^2)$

Algorithm Analysis

• 百般無聊擂台法

1.	int <i>i</i> ;	O(1) time
2.	int <i>m</i> = <i>A</i> [1];	O(1) time
3.	for (<i>i</i> = 2; <i>i</i> <= <i>n</i> ; <i>i</i> ++) {	O(n) iterations
4.	if (<i>A</i> [<i>i</i>] > <i>m</i>)	O(1) time
5.	m = A[i];	O(1) time
6.	if (<i>i</i> == <i>n</i>)	O(1) time
7.	do <i>i</i> ++ <i>n</i> times	O(n) time
8.	}	
9.	return <i>m</i> ;	O(1) time

The worst-case time complexity of 「百般無聊擂臺法」is $\Theta(n)$.

 $\frac{\text{non-tight analysis}}{3 \cdot O(1) + O(n) \cdot (3 \cdot O(1) + O(n))}$ $= O(1) + O(n) \cdot O(n)$

$$=O(1) + O(n^2)$$
$$=O(n^2)$$

tight analysis

Step 3 takes O(n) iterations for the for-loop, where only last iteration takes O(n) time and the rest take O(1) time. The steps 3-8 take time $O(n) \cdot O(1) + 1 \cdot O(n) = O(n)$

The same analysis holds for $\Omega(n)$

Algorithm Comparison

- Q: can we say that Algorithm 1 is a better algorithm than Algorithm 2 if
 - Algorithm 1 runs in O(n) time
 - Algorithm 2 runs in $O(n^2)$ time
- A: No! The algorithm with a lower upper bound on its worst-case time does not necessarily have a lower time complexity.

Comparing A and B

- Algorithm A is no worse than Algorithm B in terms of worst-case time complexity if there exists a positive function f(n) s.t.
 - Algorithm A runs in time O(f(n)) &
 - Algorithm *B* runs in time $\Omega(f(n))$ in the worst case
- Algorithm A is (strictly) better than Algorithm B in terms of worst-case time complexity if there exists a positive function f(n) s.t.
 - Algorithm A runs in time O(f(n)) &
 - Algorithm *B* runs in time $\omega(f(n))$ in the worst case

or

- Algorithm A runs in time o(f(n)) &
- Algorithm *B* runs in time $\Omega(f(n))$ in the worst case

Problem Complexity

In the worst case, what is the growth of the function the optimal algorithm of the problem takes

53

Time Complexity of a Problem

- We say that the (worst-case) time complexity of Problem P is $\Theta(f(n))$ if
- 1. The time complexity of Problem *P* is O(f(n)) & \circ There exists an O(f(n))-time algorithm that solves Problem *P*
- 2. The time complexity of Problem *P* is $\Omega(f(n))$ \circ <u>Any</u> algorithm that solves Problem *P* requires $\Omega(f(n))$ time
- The time complexity of the champion problem is $\Theta(n)$ because
- 1. The time complexity of the champion problem is O(n) &
 - o「擂臺法」is the O(n)-time algorithm
- 2. The time complexity of the champion problem is $\Omega(n)$
 - \circ Any algorithm requires $\Omega(n)$ time to make each integer in comparison at least once

Optimal Algorithm

- If Algorithm A is an optimal algorithm for Problem P in terms of worst-case time complexity
 - Algorithm A runs in time O(f(n)) &
 - The time complexity of Problem P is $\Omega(f(n))$ in the worst case
- Examples (the champion problem)
 - 擂台法 → optimal algorithm
 - It runs in O(n) time &
 - Any algorithm solving the problem requires time $\Omega(n)$ in the worst case
 - 百般無聊擂台法 → optimal algorithm
 - It runs in O(n) time &
 - Any algorithm solving the problem requires time $\Omega(n)$ in the worst case

Comparing *P* and *Q*

- Problem P is no harder than Problem Q in terms of (worst-case) time complexity if there exists a function f(n) s.t.
 - The (worst-case) time complexity of Problem P is O(f(n)) &
 - The (worst-case) time complexity of Problem Q is $\Omega(f(n))$
- Problem P is (strictly) easier than Problem Q in terms of (worst-case) time complexity if there exists a function f(n) s.t.
 - The (worst-case) time complexity of Problem P is O(f(n)) &
 - The (worst-case) time complexity of Problem Q is $\omega(f(n))$

or

- The (worst-case) time complexity of Problem P is o(f(n)) &
- The (worst-case) time complexity of Problem Q is $\Omega(f(n))$

Concluding Remarks

- Algorithm Design and Analysis Process
 - 1) Formulate a **problem**
 - 2) Develop an algorithm
 - 3) Prove the correctness
 - 4) Analyze **running time/space** requirement
- Usually brute force (暴力法) is not very efficient
- Analysis Skills
 - Prove by contradiction
 - Induction
 - Asymptotic analysis
 - Problem instance
- Algorithm Complexity
 - In the worst case, what is the growth of function <u>an algorithm</u> takes
- Problem Complexity
 - In the worst case, what is the growth of the function the optimal algorithm of the problem takes
